MR. JEFFRIES: I submit, in view of what the witness has testified to, and the statements that he has made with reference to the character of his examinations, that this question is answerable "Yes" or "No," and I give to the witness the privilege of making any such explanation afterwards as he may desire, if he thinks an explanation is necessary.

JUDGE SPRINGER: After this statement of counsel, let the witness make any answer now that he sees fit. The objection is in.

THE COMMISSIONER: Go ahead, Professor?

A. I do not see what difference there exists whether I add typhoid bouillon to the river water or whether the typhoid bacillus enters that water in the form of fresh sewage containing typhoid bacilli. I believe in fact that in my case I am introducing less organic material with the typhoid bacillus than 7465 under natural conditions where sewage containing typhoid bacilli enters the water.

Q. Now, Professor, I will ask you if it is not a fact that your analyses did not determine accurately ,the longeviety of the typhoid bacillus in the Illinois river water, according to the analyses that you made, Yes or No?

MR. TODD: I submit that the witness does not have to answer the question Yes or No.

Q. I ask you if it is not a fact that your analysis does not show the exact life of the typhoid bacillus in that water?

A. My experiments only show the life of the typhoid bacillus in that water under conditions as they exist in the laboratory.

Q. And those conditions are different from what they are in the river?

A. Yes, although I have made them as closely similar to those of the river as I could.

Q. That may be all true, but yet the conditions in the river are different than they were in the laboratory, isn't that true?

A. Yes, the conditions would be somewhat different in the test tube than they would be in the flowing water.

Q. Now professor, I will ask you if it is not necessarily true in all cases of a bacteriological examination, that the conditions are very materially different in the running stream to what they are in the laboratory? 7466

A. There are slight differences, but the principal question as to the life and possibility of existence of a pathogenic organism in the presence of conditions favorable to rapid multiplication of saprophytes would be very much alike.

Q. So when you add conditions which bring about saprophytic growth, the conditions for the destruction of the typhoid bacilli are greater in that examination than they would be in the water, aren't they, and to the extent of the additional organic matter which produce an additional saprophytic growth, the death of the typhoid bacillus in the experiment is hastened —or is hastened in the experiment?

A. I believe that the conditions in a seriously sewage polluted water, are more unfavorable for the life of the typhoid bacillus than they would be in the laboratory experiments, on account of the greater amount of organic material that would be present there. My experiments were all done with water that was not seriously polluted. I mean that the water specimens I experimented with did not contain abnormal

7467 amounts of saprophytes, like, for instance, the water in the drainage canal.

Q. Then you did not examine the life or longevity of the typhoid germ in the canal or in the water of the canal?

A. I did not.

Q. But, professor, going back now to my previous question. I don't believe you quite understood me. Confining yourself to the experiment and the bacteriological examination of the water which you made, or which you may make, or which any other bacteriologist may make, using the same system, and carrying out the same line of procedure, if it is not a fact that when you add additional organic matter in the bouillon, which produces the saprophytic organisms, if it is not a fact that this additional increased production of saprophytic organisms does not have a tendency to hasten the death of the typhoid germ and reduce the longevity of that germ in the expereiments which you make, confining this proposition now solely to the experiment?

A. To the test tube?

Q. To the test?

A. Yes, I think that is true. The real cause of any difference between laboratory experiments and natural conditions exists, however, in the fact that the excretions of saprophytes, as they multiply in the test tube, are not carried away as rapidly as they would be in the running water, or in the river
7468 water, but remain in the test tube. That is really the only point where the two could be called not identical.

Q. Except as to temperature?

A. Well, I have tried to produce the temperature of river water as nearly as I could.

Q. At the time the samples were taken?

A. Yes. It is mainly this accumulation of excretion products due to the life of the saprophytes upon organic material, which is retained in the test tube, which constitutes different conditions from those which exist in the flowing river water.

Q. Now professor, you spoke in your direct examination of the purification of the sewage from a number of European cities in the streams upon which those cities were situated.

A. Yes.

Q. You mentioned, I believe, Munich?

A. Yes.

Q. And Zurich?

A. Yes.

Q. Paris?

A. Paris.

Q. Berlin?

A. Yes.

7469 Q. And Breslau?

A. Breslau.

Q. Do you understand that the sewage from these cities is discharged into the respective rivers upon which they are located?

A. The effluent of the sewage passes into those rivers.

Q. And do you understand that this sewage is absorbed by the waters of these rivers?

A. The effluents are absorbed by the waters of these rivers.

Q. And reduced to harmless substances within the distances which you have mentioned?

A. Yes.

Q. And without injury to those residing on the rivers below the point of discharge?

A. Below the points of the purification zones which I mentioned.

Q. Now professor, if you should learn that out of the five cities mentioned, three of them have constructed intercepting sewers, pumping stations and conduits, and a complete system of sewage purification, so that no sewage from them is discharged into the rivers, but on the contrary, that all injurious and polluting matters are removed from the sewage before it is so discharged, and if you should learn that these improvements have been carried out at an expense of many 7470 millions of dollars, and were maintained at heavy annual expenditures, would this modify your views of the adequacy of dilution, to dissipate and destroy in a harmless manner the sewage of those cities and would this affect materially the value of the precedent so far as it gives a precedent, for the disposal of the Chicago sewage in the manner now practiced?

A. I have only spoken of the experiments shown at that time in regard to the zone of bacterial purification at those places, the increase of the bacteria in the waters after receiving the effluent and the gradual purification in a certain zone of the river after its exit from the city. As to these amounts which have been paid in perfecting the sewage systems, I am perfectly aware that immense sums have been spent to produce a pure water—to supply a pure water, but that does not alter the results of the bacteriological tests; that there exists a zone of bacterial purification in even the most polluted river.

Q. What effect would the information that these cities are withholding from deposit in those rivers, all of the objectionable polluting matter have upon your statements and conclusions and opinions made this morning, with reference to those cities?

A. In a general way it is attempted everywhere to avoid
7471 pollution as much as is possible, and that particularly
must be true where river water is used for drinking purposes, which under such conditions should be always filtrated.

Q. You say wherever river water is used it should always be filtrated?

A. I speak of the general proposition that any river ought to be polluted as little as possible where it is necessary that towns near by use that water for drinking purposes. As a general proposition in such cases it is not desirable to turn anything into a river.

Q. And that is from a bacteriological standpoint?

A. That is not from a bacteriological standpoint, but from a general hygienic standpoint.

Q. Supported by the science of bacteriology?

A. And by the science of hygiene.

Q. Well, has bacteriology got anything to do with the science of hygiene?

A. Yes, in so far as hygiene has originally taught us that there was no river long enough that it could purify itself of any pollution it received, and as bacteriology has proven that that dogma is not correct and that there is in every river a purification zone.

Q. I want to ask you the proposition, professor, if the
doctrine has not grown into existence, right the reverse
7472 from what you have stated; that the original belief was

among scientists, that a river running a long distance would purify itself, and that modern science has turned back on the original proposition?

A. English authorities on hygiene have taught twenty years ago that no river was long enough that it could purify itself of any pollution it received.

JUDGE SPRINGER: No river in Great Britain.

A. (Continued) And as soon as bacteriology was employed in the examination of river waters, as to the possibility of determining the quality and effects of pollutions an entirely different condition was found than that which was generally accepted by the specialist on hygiene. It was found that there is a zone of bacterial purification in every river and that sewage bacteria turned into it really disappeared within a certain distance. I, as a bacteriologist, have of course accepted that view, and, based upon my own findings in the matter, have expressed it also as my opinion that there is a bacterial purification zone in every river.

Q. Then professor, if it be true in these European rivers, that you have mentioned, and with respect to the cities 7473 that you mentioned, that when the sewage in its polluted condition was turned into those rivers that there was a zone of purification easily and readily determined, as stated by you, that these cities would spend millions of dollars for preventing that sewage from going into the river?

A. They spent millions of dollars already before this was determined.

Q. How about Paris?

A. The attempt of course in all places is to do away with as much of the pollution as possible, in only turning the effluent into the river instead of the sewage itself, but that does not prevent the great multiplication of sewage bacteria in those rivers and the figures that I have given are based upon the bacteriological examinations of those figures.

Q. And not with reference to the pathogenic bacteria that may be contained in that water?

A. No, not with reference to the pathogenic bacteria in that particular instance, only with reference to the number of bacteria—their increase in the city and their rapid decrease within a certain distance below the city—to a number of bacteria similar to that before it entered the city.

Q. So that in your testimony with reference to those rivers, you did not refer to anything of a pathogenic order?

7474 A. I did not.

Q. Then you reason, professor, that because the nonpathogenic bacteria had disappeared in those rivers, that the pathogenic bacteria had disappeared also?

A. Yes sir. For the reason which I stated several times, that saprophytic bacteria decrease much more rapidly—or as they increase more rapidly, pathogenic bacteria disappear, and that if saprophytic bacteria have decreased in number, the pathogenic bacteria must have been disappearing long before the saprophytes did.

Q. Now then, professor, I will ask you if you are acquainted with the conditions as they exist at Paris, and have for the last two years?

A. In regard to the bacteriological investigations?

Q. In regard to the manner in which the sewage is taken care of in that city and their precautions with reference to their water supply?

A. I am not familiar with the sewage disposal of Paris today, or as it exists in any of the other cities. I have only referred to these bacteriological tests with regard to the disappearance of bacteria which did occur below those cities, in the polluted river water.

Q. I will ask you, professor, if at the time that those 7475 experiments were made, that these large and enormous sums of money had been expended prior to the making of the experiments towards extracting the objectionable polluting matter from the sewage of those cities?

A. Munich was filtering its water at the time when Schlatter—when that report was made in regard to the Isar.

Q. I am not talking about the water now; we are talking about the sewage.

A. How is that question again?

(Question repeated.)

A. The investigation that was made in the Isar, as well as that of the Spree was purely made from the standpoint of determining whether any purification of the river took place or not, of the increased amount of bacteria that had been found in the river in the city, and whether that disappeared as the river flowed on.

Q. And that was made without reference to the objectionable bacteria and polluting bacteria and disease bacteria that might have been in the water in the event the sewage had been turned in?

A. It was made without any reference to pathogenic bacteria as much as I understand.

Q. Now I will ask you, professor, when those improve-
7476 ments were made if you know?

A. I don't know the various improvements that have been made in any of those places. I only know of the tests made to determine the question of the disappearance of bacteria in the polluted river water.

Q. I will ask you, professor, when it was known that there was a zone of purification in the river from a bacteriological standpoint in any river?

A. I have stated the dates of the experiments at the different cities and it is known today as it was then.

Q. And it has been known ever since the science of bacteriology has been born, has it not?

A. No, it has been known particularly since these questions were investigated in Zurich, Berlin and Munich and Breslau.

Q. And that was prior to the construction of these sewage purification plants?

A. That I am not able to state.

Q. Well, you don't know then whether it was or not?

A. No, I am not able to state that.

Q. I will ask you, professor, if you know that they are still building such plants in Europe and in this country?

A. I understand they are everywhere trying to filter the water.

7477 Q. We are talking about sewers now, and sewage.

A. The disposal of sewers into rivers has, to my knowledge, been somewhat improved by turning only the effluent into rivers, of such sewage, instead of the sewage itself.

Q. I will ask you again professor, if you are not aware that since these sewage purification plants were established in Europe which we have referred to, with reference to the particular cities about which you testified in chief, and if since it has been determined, as you say, that there is a zone of purification in every river, that various cities throughout Europe and the United States, are today expending large sums of money to purify their sewage and remove from it the objectionable material before it goes into the river. Now isn't that a fact?

A. To destroy the organic material by saprophytic overgrowth and allow the parasites or pathogenic bacteria to die before the material is poured into the river.

Q. Professor, I will have to insist on your answering my question. I don't see that that answer applies at all.

A. I will have to have that question again please.

Q. (Question read.)

A. I do not know.

Q. Professor, under those conditions and under the statements which you gave in evidence and your conclusions 7478 and opinions, would it be necessary to construct those plants?

A. I think those plants are constructed for other reasons than those of direct danger, by pathogenic bacteria entering the sewage. There is no doubt at all that the people living along the infected district, the district in which the sewage is turned into the river, are exposed to some disagreeable conditions.

Q. Don't you know as a matter of fact, as a bacteriologist, a pathologist, as a biologist, and as a scientific man, that the sole object that those cities have in purifying their sewage before they discharge it into the river, is to remove from it the objectionable and deleterious material in the construction of those sewage purification plants, so that the water would not be rendered objectionable to their neighbors.

JUDGE SPRINGER: I object to this question upon the ground that it assumes that the cities referred to which may have established these sewage purification plants, have not done so with a view to purifying their own water supply, but merely their drainage system, that they still get their water supply from above the place where their own sewage empties into the river.

Q. (Question read.)

JUDGE SPRINGER: Below them on the stream, you mean?

7479 MR. JEFFRIES: Yes.

A. The filtration even under those most favorable circumstances, will allow some bacteria to pass through, and some of them might be pathogenic.

Q. Professor, answer my question.

A. They would still get into the river.

Q. That doesen't make any difference, I want my question answered.

(Question repeated.)

A. There are many features that may make a water objectionable and I don't see that I can answer that question any more thoroughly than I have because I am not an epidemiologist.

Q. Do you consider it a question of epidemiology or something with which you are not acquainted?

A. I consider that a question which is simply a matter of prejudice in a good many respects. It is objectionable to use a water which smells because sewage has been turned into it, and there are a great many reasons why people living near the source of such pollution should go to great expense to avoid such nuisance.

7480 Q. Now do you consider in that answer, the effect of pathogenic germs upon the health of the people who use that water, as one of the reasons for the constructions of those plants?

A. You ask me about imaginary plants.

Q. I ask you about real plants?

A. That I have testified I don't know anything about.

Q. I ask you about real plants which you admitted were in existence.

A. Now give me that last question.

(Previous questions and answers read).

Q. MR JEFFRIES: I will state this, professor, that in your statement as to the reason for the construction of these plants, you mentioned many things, but for some reason you eliminated the question of pathogenic germs and water borne diseases, and the effect that they would have upon the people using that water. Now I want to know whether you include that as one of the reasons for the construction of these plants or whether it is material or not?

A. I can only say that I have only testified to things that I know, and you now ask me to testify on things that I don't know. That is with regard to sewage disposal plants, and their efficiency in preventing contamination of rivers by pathogenic germs. If you will kindly ask me questions as to things that I have testified to I will try and answer them.

7481 Q. Then professor, you say that you don't know anything about the rivers in Europe about which you testified this morning, or the cities that are situated upon their banks?

JUDGE SPRINGER: I object to that question because it assumes a condition that the witness does not mean.

A. I have not testified as to the plants, as to the sewage systems or as to anything of that order. I simply testified as to some experiments made in those cities with regard to the disappearance of bacteria in the polluted rivers after they have received the sewage of those cities.

Q. Now do you know that they receive the sewage of the cities?

A. They receive the effluent as well as a great deal of sewage, from those cities.

Q. Do you know that?

A. I know that from the literature, yes.

Q. Would you be surprised, professor, to learn that the opposite was the case?

A. I understand what you mean. You mean where they receive the effluent. I spoke of that also, in my testimony this morning, when they received only the effluent. I admit that.

JUDGE SPRINGER: I submit that at the time this Paris experiment was made, that the sewage of the entire city of Paris, of 2,500,000 people, was discharged into the river Seine, and that the literature will show that fact,—or four-fifths of 7482 the sewage of 2,500,000 people, which would be 2,000,000 people anyway.

Q. MR. JEFFRIES: Professor, according then to the literature from which you obtained your information, this zone of purification was known in the river into which the sewage from Paris was deposited, at the time the experiment was made; isn't that true?

A. Yes.

JUDGE SPRINGER: I further desire to submit here that this examination is not fair to the witness for the reason that the zone of purification of Paris was fixed at 40 miles below the city. It is well known by everybody that below Paris is a very populous country, and that the people living below the city have some rights and that the city was trying to protect those people as well as their own inhabitants, in Paris.

MR. JEFFRIES: I suggest in response to the counsel's suggestion, that the city of St. Louis in the State of Missouri belongs to the United States. I suggest also that if the present rate of increase in population continues, it will not be many years until the territory between the city of Chicago and the city of St. Louis, and the territory in the Illinois river valley and the Mississippi valley will be as populous as that at Paris
or at any other place in the civilized world; that that is
7483 a matter of future prospects and future conditions, and
we are willing to submit to counsel's statement and take that in view in our consideration of this case.

Q. Professor, I will ask you if you don't know that in this country and in Europe there have been various plants of the character about which we have been speaking, plants for the purpose of removing the objectionable substances, the disease producing substances from the sewage of cities, in order to protect the public health of the people who are exposed to the use of the waters of the rivers into which the sewage formerly was discharged?

A. Yes, I know that in a general way.

Q. I want to ask you this question. If the purification, or rather the removal of the objectionable material from sewage of a large and populous city would not make the sanitary condition of the water into which those sewage discharges formerly entered a better sanitary condition than the water was in while the sewage in its raw condition was being discharged into the river?

JUDGE SPRINGER: I object to the question on the ground that it does not fix a point down the river at which the objectionable features might be eliminated by the means indicated in this examination heretofore, in regard to the Illinois river

7484 between here and Peoria for instance.

Q. (Question read).

MR. TODD: At the places of discharge?

MR. JEFFRIES: The water of that river.

Q. (Question read).

A. I think as a general proposition that sewage filtered of course would be more favorable than sewage not filtered when it went into the river.

Q. But with the raw sewage being deposited into the river, is it not a fact that it renders the water in the river much more objectionable than it is without the sewage?

A. Raw sewage? I do not quite understand what you mean by raw sewage. Now is that sewage that has remained, stood in the sewers for some time or is that sewage as found in the drainage canal?

Q. I mean professor, isn't it a fact that the discharge of the sewage such as ordinarily is discharged from the sewers of the large and populous cities of this country or any other country, without treatment of some kind, into a river, renders the water in that river in a less sanitary condition than without the sewage?

A. There is no question about that in a general way.

7485 Q. Well, that is just it exactly.

A. The river is better without sewage than with it.

Q. Professor, do you know whether or not the city of Peoria abandoned the Illinois river as its water supply some years ago?

A. I do not.

Q. Do you know the condition of the Illinois river prior to the opening of the Chicago drainage canal as far as Peoria?

A. I do not.

Q. You have been at Peoria?

A. I have lately been down the river—down the canal and the Illinois river to St. Louis. That is the first time I have seen it.

Q. From your analyses would you think it necessary for them to abandon the Illinois river as a water supply?

JUDGE SPRINGER: Who abandons it?

MR. JEFFRIES: The city of Peoria.

A. Bacteriologically considered, not.

Q. As a sanitarian would you—oh, you don't speak as a sanitarian.

A. No. In other words, the question—may I say why?

Q. Yes.

7486 A. A water may be chemically and it may be physically pure, and yet it may contain pathogenic bacteria. Now then the bacteriologist would condemn that, whereas the chemist and the sanitarian does not make those examinations and would consider that a pretty fair supply. Bacteriologically I might call a water bad that contains only two pathogenic germs per cubic centimeter, whereas that would not be considered bad under normal conditions and vice versa where only a quantitative test is made a water containing we will say 10,000, or 50,000 germs might be called generally bad, when in fact those are nothing but water bacteria.

Q. Now professor, when you condemn water from a bacteriological standpoint that contains two germs or two bacteria per cubic centimeter, you would do that because of the condition of the test itself, or would you take into consideration your knowledge of the stream and the stream flow?

A. If I found pathogenic bacteria anywhere I would consider that substance, whether it be food or water, as dangerous, and to be prohibited from drinking it.

Q. Then if I understand you professor correctly, it is not a question of the number of the bacteria of all kinds and classes that are found in the water that condemns it?

A. No sir.

Q. But it is the presence of pathogenic bacteria?

7487 A. The pathogenic bacteria, or the presence of bacteria commonly found in sewage.

Q. Now then, professor, in passing upon that proposition as a practical question, aside from the laboratory, I will ask you if you do not think it is essential to take into consideration the opportunity for those pathogenic germs to be found in the water as well as the fact that they are not really found there, in passing upon the sanitary condition of the water?

A. Pathogenic germs may be found in the water.

Q. Then you must take into consideration the opportunity of their getting there if they are being found there?

A. Certainly.

7488 Q. Then professor, taking those things into consideration, must you not in addition take into consideration the temperature of the water at all times of the year, the stream flow of the water at all times of the year, and the condition of the river with reference to low stages of the water and high stages, freshets and floods?

A. In passing a general opinion as to the potability and safety of water for drinking purposes that should all be included, as well as the chemical examination, as well as the physical, to arrive at the potability of water.

Q. Now I will ask you this question: if you found a pathogenic germ in one water, at the mouth of one stream, for instance, we will designate that as stream A, and you find pathogenic germs in stream B, and the pathogenic germ in the sample of water taken from stream C; now in order to pass upon the relative amount of pollution that may be found in those rivers, the relative character and the comparative character of the water, or the sanitary condition of the water in those rivers, wouldn't you consider the source and the extent of known polluted matters of a deleterious character, entering those streams?

A. Yes, I would consider that also.

Q. And that too, without reference to the number of bacteria or characters that you may find in any of the waters? 7489

A. Yes sir.

Q. Now professor, in passing your judgment and opinion upon the sanitary condition of the water in the Illinois river at Peoria or above Peoria, I will ask you if you took into consideration those facts or the facts contained in that preceding question?

A. I only expressed an opinion in regard to the bacteriological purification at that place and the absence of pathogenic bacteria.

Q. Then your opinion is based solely and alone upon your bacteriological tests, the results of the analyses of the water made by you in your laboratory here in Chicago?

A. With regard to the bacteriological flora at that place.

Q. And from that bacteriological flora you express that judgment and drew certain conclusions, did you not?

A. Only in regard to the bacterial purification, but not with regard to any other purification.

Q. So then you do not know whether the water at that point, above Peoria or the water at Grafton, or the water at St. Louis is pure or not, or free from pathogenic germs?

A. A water may be objectionable besides that of the
7490 bacterial contents for physical reasons purely, and it may
be objectionable for chemical reasons. My examination
refers purely to the bacteriological side.

Q. Now professor, I want to ask you if from a bacteriological standpoint, bacteriologists do not determine the physical stability of a water from its bacterial content, and if they do not, of what benefit is bacteriology in determining the sanitary condition of any water?

A. You do not determine the sanitary condition of any water purely by bacteriology. You only determine the bacterial pollution of a river or lake water by bacteriology and not any other element. Bacteriology has nothing to do with the final judgment. We leave that to the sanitarian to decide upon all the factors which he has collected from all different sciences. A water may be bacteriologically pure and may be chemically impure and vice versa.

Q. Then professor, you want to be understood as saying or speaking as a bacteriologist purely and simply, is that true, and not one step farther?

A. The opinions I have expressed all the time are purely on bacteriological grounds, and every judgment that I may have expressed in this matter is purely based on my experience as a bacteriologist and also my experience with the water of this
river and only refers to the contents of the bacteria in the
7491 river and not to the chemical or physical aspects of the
question, whether the water is potable or not.

Q. Now then, professor, confining yourself to bacteriology and confining your opinion and judgment and your conclusions as to the sanitary condition of the water in the Illinois river at Peoria and at other points, I want to ask you if it would not be necessary before you could express a reliable and adequate conclusion as to the condition of that water, for you to first have a bacteriological analysis of that water from one end of the year to the other, taking into consideration the various changes in temperature, cold weather, hot weather, warm weather, flood times, low water seasons and local conditions from one end of the river to the other, and if it is not necessary to have all this information. What is there in the analysis which you have made, which leads you to believe and which furnishes you sufficient information to pass judgment upon that water?

A. I did not pass judgment on that water. I examined a number of specimens between February and October from each place and mainly for the presence of pathogenic bacteria. I was not to pass judgment on the potability of the water, but I was to determine during this period what pathogenic or disease producing bacteria could be found in the specimens submitted to me for examination. 7492 As to the rest of the question, I am willing to say that the more numerous the examinations, the better the final conclusions are. There is no doubt that 10,000 examinations are better than ten.

Q. How about the necessity of having the water examined bacteriologically and bacterially at all seasons of the year?

A. That is another point that is desirable.

Q. Now professor, do I understand you to say that you have not stated in evidence that the sewage of Chicago has any influence whatever upon the sanitary condition of the water in the Mississippi river at the chain of rocks in St. Louis?

A. Yes, and I have given my reasons for that opinion.

Q. And that as I understood you a moment ago, was a conclusion based solely upon your bacterial analyses and what they showed?

A. Of the water, no. That was based purely and solely upon the experiments in the laboratory as to the behavior of pathogenic bacteria in water generally, and my findings about the gradual disappearance of pathogenic bacteria in the presence of large numbers of saprophytic bacteria.

Q. But the conclusion which you came to, as you stated, was based upon your analysis, bacteriologically speaking, 7493 of that water and I want to ask you if you did not state a few moments ago that that opinion was based solely upon that examination?

MR. TODD: I object to the question as it is double-barreled. The first question is an assertion of what counsel understands. The second question is a straight question and I submit that the two questions ought to be separated.

MR. JEFFRIES: The witness can separate them if he wants to. He is an intelligent witness.

JUDGE SPRINGER: Read the first part of it and answer that first.

(First part of question read to witness)

A. My opinion as to the bacteriological purification of the river was based upon the findings in this report, to the State Board of Health.

(Last part of question repeated to witness)

A. I do not remember that I said I was basing my opinion solely on that.

7494 Q. I will ask you this question, professor, if you did not state a few moments ago that in determining the sanitary condition of the water from a bacteriological standpoint that it was necessary for you to take into consideration the temperature of the water at all seasons of the year, the stage of the water the flood seasons, winter season, summer season, the extent of the polluting material entering that river, and that you stated you had not taken such facts into consideration in forming these conclusions?

A. Yes. I have not. I did not determine the sanitary condition of the water. I determined the bacterial purification.

Q. Now professor, I believe you stated that the pathogenic germs live longer as the amount of organic matter is less. In other words a decreasing amount of organic matter meant longer life and greater longevity to pathogenic germs?

A. I made the statement that when organic matters increase, that the saprophytic bacteria multiply more rapidly and overgrow the pathogenic bacteria, and that they therefore die sooner in the presence of large quantities of organic matter than the saprophytes; than they would if there were no saprophytes and large quantities of organic material present.

Q. Now professor, this being so, how would the life of the pathogenic germs compare in the water of the Chicago drainage canal and the Illinois river as they now are, that is
7495 as the rivers now are, as compared with the life of germs
in the water of the Illinois and Michigan canal, and in the Chicago river prior to the opening of the drainage canal?

JUDGE SPRINGER: I object to the question on the ground that the witness has stated that he was not familiar with the waters of the drainage canal or the Illinois river prior to the opening of the canal.

A. Nor with the Illinois and Michigan canal and the conditions of the Chicago river.

MR. JEFFRIES: Now professor, assuming that the sewage of Chicago prior to the opening of the canal flowed into the Chicago river, its various forks and branches, that a certain portion of it was pumped into a canal several miles in length which flowed a distance of twenty or more miles without dilution and at a much less rate than is now maintained in the main drainage canal; that there was pumped on the average about 35,000 cubic feet per minute of this sewage polluted water which has been characterized at times as an open sewer, and that this volume of water was pumped, and that the current at times in the Chicago river reversed its natural flow from the west to Lake Michigan, so that the river flowed in an opposite direction; that this volume of 35,000 cubic feet of water and sewage per minute, represented about three-fourths of the sew-
4796 age of Chicago containing the same amount of sewage as
now flows down the main drainage canal diluted with 250,000 cubic feet of water per minute, how would the life of a pathogenic germ compare, in the water of the Chicago drainage canal and the Chicago river and the Illinois and Michigan canal under the assumption I have just stated, prior to the opening of the main drainage canal?

A. Well, I will simply say that in a long canal, 30 miles long, sewage entering and remaining more or less stagnant, will allow the same multiplication of saprophytes that we find here in the drainage canal and the same destruction of pathogenic bacteria.

Q. Considering, professor, the greater concentration of the polluted matter,—sewage for instance—in the Chicago river prior to the opening of the canal than there is now in the main drainage canal, would not the conditions be less favorable in the Chicago river prior to the opening of the canal for the life and vitality of pathogenic germs than now?

A. I can answer that in a general way. The slower the flow and the less dilution and the more organic matter, the more saprophytes, the sooner the death of the pathogenic bacteria. 7497

Q. So that, professor, if you take a gallon of water and dilute it with a pint of sewage the conditions for the disappearance of pathogenic germs would be more favorable in that composition than it would to take a barrel of water and dilute it with a pint of sewage?

A. Yes, I think that would be the case.

Q. So that whatever pathogenic germs that a pint may have contained, the pint that was poured into the gallon of water, they would disappear much more rapidly than the same pathogenic germs would were they deposited in a barrel of water?

A. If the same amount of sewage had been deposited in a barrel of water. The more sewage, the more organic material, the better opportunities for saprophytic life. I take it now you are speaking of conditions at the usual low temperature of water.

Q. Then, professor, assuming that the same amount of sewage is discharged into the two streams, the one with the flow of 35,000 cubic feet per minute, the other with the flow of 250,000 cubic feet per minute; the facilities for the disappearance of pathogenic germs are better and more favorable in the smaller stream than it would be for the larger stream, isn't that true?

A. In the larger stream the dilution would be so much greater.

7498 Q. Aside from the dilution?

A. Yes, but that is an important factor.

Q. We are talking now, aside from dilution.

JUDGE SPRINGER: You cannot eliminate that.

Q. MR. JEFFRIES: We are talking about the life of the germ, which eliminates the dilution entirely.

JUDGE SPRINGER: I submit that the question which has just been put speaks of a dilution of 250,000 cubic feet of water per minute in the drainage canal and that therefore it is not eliminated.

MR. JEFFRIES: I suggest that this question is put for the purpose of showing the opportunity for the pathogenic germs to live in running streams?

A. I will say that the greater the dilution, the further separated of course will be the pathogenic germs, and the less will be the bad effect upon them of the rapidly multiplying saphrophytes and their products, and therefore as a general proposition a pathogenic germ ought to live longer, the purer the water.

Q. And from your scientific information there is no reason why it would not live longer, is there? And you are ready to believe it will live longer?

7499 A. My opinion is that a pathogenic germ will live longer in water that doesn't contain any other bacteria at all, than in water which contains organic material and saprophytic bacteria. The greater the dilution, the further apart will be the individual bacteria and the less effect the growth of the saprophytic bacteria exert upon pathogenic germs.

ADJOURNED until 10:00 A. M., Monday, October 5th, 1903.

7500 10:00 A. M., Monday, October 5, 1903. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

By agreement of counsel, witness, Professor F. Robert Zeit, was temporarily withdrawn, in order to take the testimony of witness W. E. Lautz.

W. E. LAUTZ,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer and testified as follows:

Q. What is your name, residence and occupation?

A. W. E. Lautz, Pekin, Illinois.

Q. How long have you resided in Pekin?

A. All my life.

Q. State whether during the year 1901 you received any instructions from any person in regard to taking samples of water from the Illinois river?

A. Yes sir, I did.

7501 Q. From whom did you receive those instructions?

A. Mr. Irons and Mr. Schule.

Q. For whom were they working, do you know?

A. As far as I know for the drainage canal commission.

Q. Were you employed by these two gentlemen to take samples from the Illinois river?

A. Yes.

Q. Will you please state then what instructions you received from them and the place at which you took the samples and what you did with them?

A. The point at which I took the samples was about a mile and a half down the river from Pekin.

Q. Below Pekin?

A. Yes sir, and I would get so many bottles to be filled each day, with a mechanical contrivance to fill that bottle, and recork it while it was held three or four feet below the surface of the water.

Q. What was the capacity of it, of each of these bottles?

A. The chemical sample was a large bottle, I think about a gallon.

Q. And the others?

A. The others were smaller bottles, I should judge they held about eight or ten ounces. I could not say as to that however.

7502 Q. State what you did with the samples when you took them from the water?

A. I packed them in ice and shipped them by express, part of them to Professor Palmer at Champaign, and some of them I took in person to Mr. Schule, at his office in Peoria.

Q. How did you ship them, in what manner?

A. They were packed in excelsior and ice, and securely sealed and shipped by express.

Q. From what point?

A. Pekin.

Q. State now distinctly, how you took the samples of water, what precautions you took if any, in regard to getting the sample out of the river?

A. I first fastened the bottle in the contrivance for the removal of the stopper, and the lowering of the bottle below the surface. My instructions were to be very careful that my hands did not come in contact with the mouth of the bottle or the stopper. I was always very careful to see that that bottle was opened and closed while it was below the surface.

Q. And they were filled below the surface?

A. Yes.

Q. And stoppered before you raised them out of the water?

7503 A. Yes sir.

Q. What kind of a stopper was it?

A. Glass stopper.

Q. Which size of the bottles did you ship to Professor Palmer?

A. Both sizes.

Q. Both sizes?

A. Yes sir.

Q. What kind did you give then to Mr. Schule?

A. Both sizes.

Q. Well, how did you give those to Schule, did you state?

A. I took them up in person.

Q. Took them up to Peoria in person ?

A. Yes sir.

Q. Did you put any tag upon the bottle for the purpose of identifying?

A. I did, sir.

Q. What was the nature of it?

A. It was a tin tag with numerals stamped in the tin, these were pierced by a hole and I stuck a wire through the hole and around the neck of the bottle. The neck of the bottle was covered by a cloth, a sort of a canvass, and that wire was drawn up very securely and run through the lead similar to a 7504 freight car seal. That is as near as I can describe it, and the lead was smashed so that it was held securely.

Q. Did you receive any blank cards for the purpose of making your notations upon?

A. Yes sir, I did.

Q. In reference to each bottle of water taken?

A. I did.

Q. Look at that card and see if it is one of them?

A. Yes sir, it is.

Q. Look at that package and see if they are those that you made out?

A. I think they are all just as I made them out, in my handwriting.

Q. Now state when the first sample was taken, according to the dates there entered?

A. These are mixed up. I don't know that I can find the first card. My first sample was taken I think on the 16th day of September, 1901.

Q. When was the last taken?

A. On the 31st day of December, 1901.

Q. From your examination of those cards, state whether they are the cards that you made at the time,—the blanks of which you filled out?

7505 A. They were the cards I made at the time, the cards were filled out at the point where I took the sample each day.

Q. Do those cards then as filled out present a true statement of the conditions which you noted at the time, upon them?

A. They do, sir, yes sir.

Q. And the true date?

A. Yes sir, the true date.

Q. State what was included in the card that you took, what facts?

A. The temperature of the air, I took each day, and the temperature of the water, and the directions of the current if I could detect them, and the appearance as to rain, and also the turbidity of the water.

Q. State how far from the shore or either shore was it in the stream that you took the sample?

A. Why the current at that point was quite close to the western shore of the river, that is, the Peoria county side. I should judge that it was 100 feet from the Peoria county shore at that point.

Q. Was it intended to be in the mid-stream?

A. No sir, it was intended to be in the current.

Q. I mean in the mid-current?

A. In the mid-current.

7506 Q. How deep below the surface of the water did you take your samples, as you state?

A. About the full depth of the contrivance, I think that was three and a half to four feet.

Q. Was the sewage of Pekin entering the river at the place where you took these samples,—above the point?

A. Yes sir.

Q. You took them below the Pekin sewage?

A. Yes sir.

Q. State whether there had been at the place where you took these samples, a complete mixing of the water in the river—of the Peoria and Pekin sewage, with the water in the river?

A. As to the Peoria mixture, I think likely that was quite thoroughly mixed, but the Pekin sewage—

MR. JEFFRIES: I object to the question for the reason that the witness has not properly qualified himself to be able to give any testimony that would be reliable upon the question at hand.

Q. JUDGE SPRINGER: You can state from your personal observation of the water so far as it appeared to you?

A. I know that the Pekin sewage was not mixed with the water.

Q. The Pekin sewage was not mixed?

A. No sir.

7507 Q. How could you tell that?

A. It was in the fall of the year that I took these samples, and the sewage was of a higher temperature than the temperature of the river water. You could see the steam arising from the sewage in the water along the Tazewell county shore of the river, and hugging that shore all the way down. It didn't come out into the current.

MR. JEFFRIES: I move to strike out the question and answer for the reason stated in my previous objection.

Q. Which side of the river is Tazewell on?

A. The east side.

Q. The side opposite from that where you took the samples?

A. Yes, sir, and that is where the current was.

JUDGE SPRINGER: We present this package of tickets, consisting of 48, numbered consecutively as appears thereon, and ask that they be marked Defendant Sanitary District of Chicago's Exhibit No. 22 for identification.

Received and so marked by the Commissioner.

CROSS-EXAMINATION, by Mr. Jeffries.

Q. Did you take any other samples than those to which you have testified?

A. No, sir.

7508 Q. Did you take samples of water from any other points than that to which you have testified?

A. No, sir.

Q. And you always took them from the same place in the river?

A. From the same points.

Q. What was the character of this piece of machinery that you used to take these samples with?

A. It was a rod or hollow tubing that branched out in the form of a loop, large enough to take the bottle at the bottom. It sat upon a sort of a plate at the end of that fork. Then it had a clamp right at the top of the fork to engage the cork with a wire coming through the hollow handle or cross-piece on the top which, when the cork was attached to the clamp and the bottle immersed all you had to do to take out the cork was to pull on the wire coming up through the hollow handle.

Q. Now, state whether or not you rinsed the bottles?

A. No, sir. Why, I rinsed them at the time—no doubt at the same time there, with the river water, before doing anything, I think.

Q. Before what?

A. Just as soon as I got down there I immersed the bottle full.

Q. With your hand?

A. No, sir, with the machine.

7509 Q. Then what did you do?

A. Put on the cork below the surface of the water and pulled it up and put that canvas covering on top and tied that down and put it in the compartment.

Q. Yes, but that was after you rinsed the bottle?

A. No, sir.

Q. State how you rinsed the bottle?

A. I didn't rinse the bottle.

Q. I will ask you if instructions were not given you to rinse them, and if the instructions upon the card which you used, which you said were your instructions, did not state that the bottles must be rinsed?

A. I fail to recall definitely whether I did or not.

Q. Then if the card does state that the bottles should be rinsed before they are filled, to be shipped, you did not carry out the instructions on the back of the card, did you?

A. I carried out the instructions on the backs of the cards to the letter.

Q. But you didn't rinse the bottles?

A. As I recall it I did not.

Q. I will ask you to examine the card and see whether or not it does not require that the bottles should be rinsed before they are filled for shipment.

7510 JUDGE SPRINGER: On the back of the card.

(Witness examined card.)

A. I notice sir, that the instructions are that the bottles should be rinsed.

Q. Well, now, did you do that?

A. Yes, sir.

Q. Are you sure you did?

A. Yes, sir, if these were the instructions, I followed them.

Q. Still, don't you know aside from the card itself whether you followed them or not?

A. As I remember, I think I did.

Q. Do you remember whether you rinsed the bottles or not?

A. Yes.

Q. Now state just how you did that?

A. It was rinsed with river water.

Q. Well, how did you do it?

A. That is to put the bottle below the surface and take a little water in and pour it out, and immerse it again.

Q. What did you do with the stopper while you were rinsign the bottles?

A. It was held some way in my hand.

Q. Or you would lay it down?

7511 A. No, sir. I was very careful of that stopper, that it did not come in contact with anything else under my instructions.

Q. Except your hands?

A. Well, I had to take hold of the top of the stopper to remove it of course.

Q. You remember very distinctly now of having rinsed the bottles,—all those bottles, every one of them?

A. Yes, sir.

Q. As a matter of fact, don't you know that you did not rinse the bottles?

A. No, sir, I do not. I rinsed them.

Q. So then you wish to be corrected in your statement that you did not rinse them?

A. Why, there is no statement to correct. I said I rinsed them.

Q. Didn't you state a few minutes ago that you did not rinse them?

A. I don't think I did, sir.

JUDGE SPRINGER: Just read that.

(Previous questions and answers read.)

JUDGE SPRINGER: Now, since refreshing your memory, can you state whether you did or not?

7512 A. I can say that I did if those were the instructions on the backs of those cards. Those were my instructions and I followed the instructions absolutely.

Q. MR. JEFFRIES: All that you know now is that you did just what those cards say on the back and nothing more. You don't remember anything else that you did do, is that true?

A. Those were my instructions on the back. I know I followed those.

Q. How deep under the surface of the water did you go to get the water in the bottles that you rinsed them with?

A. About the depth of the mechanical contrivance.

Q. The same depth that you got the samples?

A. Yes, sir.

Q. Where did you get these bottles that you used

A. They were shipped to me by Mr. Schule. Mr. Schule or Professor Palmer, before I went up there.

Q. Went up where?

A. When I took the sample to Mr. Schule, at his office in Peoria, he had a bottle ready for me to return with empty.

Q. You carried them from Pekin up to Peoria?

A. Yes, sir.

Q. You first went to Peoria and got the bottles and then
took them down to Pekin and filled them and then carried
7513 them back to Peoria.

A. No, when I took the full sample up I carried the empty cases back the following morning and took these down and filled them, and repeated the performance each day.

Q. What condition were they in when you got them?

A. They were all packed in excelsior in cases. The tops were securely tied on with rubber cloth.

Q. Did you open them before you left Peoria?

A. No, sir, I never touched them at all until I got down to the places where I was to take the samples.

Q. When did you pack ice around the samples?

A. At the boat landing in Pekin.

Q. You went out into the river and got the sample, brought it to shore and then packed ice around it?

A. I took the cases and packed them with ice at the boat landing in Pekin when I went down with it.

Q. Before you put the water in?

A. Before I put the water in, yes. The case that I packed the sample in was in two compartments, one compartment for ice and one for the bottle.

Q. Did you pack all the samples at the same time before you put any of them in ice—how many samples did you take each time?

7514 A. Three days a week I would ship to Professor Palmer at Champaign. On those days my samples were doubled; on the other days I only took Mr. Schule's samples.

Q. Now, then, when you took more than one set of samples, you took them all at the same time?

A. Yes, sir.

Q. And carried them from the point in the river where the samples were taken, to the shore, and packed them?

A. No, sir, all the packing was done right in the boat there on the river.

Q. Then as you collected the samples you packed them, is that it?

A. Yes, sir. All I had to do when I had a bottle full was to shove it down in the compartment and close the lid.

Q. Well, you always did that, did you?

A. Yes, sir.

Q. Did you have any trouble getting out to where you took the samples?

A. No, sir.

Q. How did you get out?

A. In a row boat.

Q. Always in a row boat?

A. Always in a row boat.

7515 Q. There was no ice on the river when you took the samples?

A. No, sir.

(Signature waived.)

7516 PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination, by Mr. Jeffries, and testified as follows:

Q. Professor, what is pathology?

A. Pathology is the study of disease, of the diseased organs, briefly.

Q. Is that all there is to it?

A. Well, if I shall be more explicit, pathology includes all the causes and manifestations of disease, as well as their results, a study of tissue changes and disturbances of functions of various organs.

Q. I will ask you now if in this connection you have studied the causation of diseases?

A. I have not in that connection studied the causation of diseases as much as I have in connection with bacteriology —infectious diseases you refer to?

Q. Well, I have reference to all kinds of diseases?

A. Then I can answer your question with yes. As far as infectious diseases are concerned, I have studied those more from the standpoint of a bacteriologist.

Q. So, then, so far as the causation of infectious disease is
concerned, as applied to and as connected with pathology,
7517 you have given it no other study than that which you have
made from a bacteriological standpoint, is that true?

A. I have studied infectious diseases with regard to their cause, with regard to the manner in which these causes infect the human organisms; with regards to the ways in which these cause, mostly micro-organisms, are spread and find entrance into the human body, and through what avenues they enter the human body and what changes they produce in the organs or tissues of the human body and animal body.

Q. Now, Professor, I want you to state the extent of your studies with reference to the causation of infectious diseases and more particularly diseases known as water-borne diseases?

A. The principal study of such diseases consisted in studying the disease itself and the biology of the germ—which caused it. Just repeat that question, please. I don't know if I have answered it fully.

Q. (Question repeated.)

A. With regard to the causation of those diseases, the cause is the infecting organism, and I have studied the infecting organisms,—the biology of the infecting organism as well, as I stated before, how it enters the human body, and the changes
that it produces there.

7518 Q. Now I will ask you, Professor, if you have studied
the biology of the infecting germ as obtained from the
water in which it may be found, or have you studied the biology of that germ as you found it in the laboratory, and as it came from the excreta of a patient suffering with that particular disease?

A. I have studied the biology of the organism as it came from the human body.

Q. And have you studied the biology of the organism as it is contained in the water infected with the germ of disease?

A. Yes, I have also studied the behavior of pahtogenic bacteria or disease producing micro-organisms in water.

Q. Now, then, I want you to state, Professor, clearly the full history of your investigations and your experiments on that subject and along that line?

A. With regard to the behavior of pathogenic bacteria in water, I found that when pathogenic bacteria are put into water containing much organic material, and polluted with sewage bacteria or containing many water bacteria, and the mixture is kept at a low temperature, as low as ten to twelve degrees centigrade, the water bacteria multiply rapidly and the other saprophytic bacteria multiply and overgrow the pathogenic bacteria which then die out quickly. If the temperature is somewhat
higher, say the temperature of the room, the other condi-
7519 tions being the same, the saprophytes grow—multiply
most and overgrow the pathogenic bacteria to such an extent that they disappear also within several days. When the pathogenic bacteria are put into pure water,—I mean sterilized water, containing no bacteria of any kind, they will live for weeks.

Q. Four weeks, you say, or for weeks?

A. For weeks—three or four weeks even, even if there is no organic material present. If there is a slight amount of organic material present, and the temperature is favorable, they will even increase and they will live in there for weeks. If we take pathogenic bacteria and put them into a so-called pure and potable water, a water containing no saprophytic bacteria, but only water bacteria, such as are commonly found in water, innocent water bacteria, and keep the temperature at that of the water or even at that of the room, there is a great multiplication of water bacteria only. I am speaking now of a water which is almost free of organic material. Water bacteria seem to be able to grow more rapidly, even in the absence of any organic material, whereas, saprophytes will grow better and increase more
when organic material is present, so that even in a pure
7520 water where there are no saprophytic bacteria present, a
rapid multiplication of the common water bacteria takes place and the pathogenic bacteria are overgrown and disappear. The experiments that I have made were mostly with Lake Michigan water, and also with sterilized water, and finally they were

made with the waters of the Illinois river above Grafton, with the Mississippi river just before the Illinois enters it, and of the Missouri above the mouth of the Missouri. Those three waters contained great numbers of saprophytic bacteria and the pathogenic bacteria died out quicker than they did in Lake Michigan water.

JUDGE SPRINGER: Can you state within how much time?

A. In five to six days. I might add here, that I also know this to be a common experience. For instance, in the water of the river Ganges, and the river Yumma, which is very rich in organic material, the vibrio of Asiatic cholera will die in two to four hours, according to the experiments of Hankin. I have in none of my experiments found any such conditions. The shortest periods of life I have observed were five days in the waters that I have examined.

Q. Have you made any experiments with the germ of cholera?

A. I have. In these experiments I have always used the typhoid bacillus, the vibrio of Asiatic cholera, the staphylococcus aureaus and the anthrax bacillus.

7521 Q. Now, Professor, state where you got your cultures of typhoid bacilli?

A. The cultures that I have used were anywhere from the fifteenth to the thirtieth generation from a case of typhoid fever, whnere I obtained them in the following manner: At a post-mortem, the spleen was seared with a red-hot spatula and a sterile knife was inserted into this area. A platinum loop was then inserted into the spleen and inoculations made upon agar slants. These agar slants were grown in the incubator 24 hours and then showed a pure culture of the typhoid bacillus. By "generations" I mean that I inoculated another tube of agar from the first. This was then the second generation. If from that tube a third one was made, that was called the third, and so on. The typhoid bacilli I used in the experiments were the fifteenth to the thirtieth generation, possibly more, in some instances.

Q. Now, Professor, I will ask you if you know whether or not it is not a fact that these low generations of typhoid bacilli were less hardy, less vigorous and shorter lived than those which came from the patient sick of that disease?

A. They, no doubt, in passing so many generations lose some of their virulence, but they were still alive. They might grow even better in the later generations, although they 7522 lost their virulence entirely. They may be alive and show all the characteristic biological factors by which we recognize the typhoid bacillus even if their virulence was lost.

Q. Then you could not say that the later experiments which you made were virulent or not.

A. I am unable to state with regard to these experiments whether in all cases the typhoid bacillus I used was a virulent bacillus or not, because I have not in all cases tested its virulence upon guinea pigs. The problem was simply to find the typhoid bacillus in water which I had inoculated with it to see whether it would remain alive in water. The problem was not as to whether it would lose or increase its virulence in that water.

Q. Professor, how do you keep the typhoid bacilli alive in the laboratory for a number of years?

A. We cannot do it.

Q. How do you keep them alive for any length of time?

A. We keep them alive in this way: We inoculate agar slants by means of a platinum wire. This is grown in the incubator over night, at the most 24 hours. After 24 hours we have along the streak of inoculation a colony which looks somewhat elevated, glistening and is probably not wider than one-sixteenth of an inch, to about one-eighth of an inch along the whole streak of inoculation, and now we place this culture 7523 in the ice box to prevent it from dying. If we would allow the culture to stand in the room or allow it to remain in the incubator, there would be an overgrowth of bacteria and they would die in their own poisons. Cultures that are allowed to remain in the temperature of the room will generally die very soon, so we do not allow them to grow longer than one night in the incubator, and then in this condition in the ice chest or in the cellar, they will keep alive from between three to six weeks. Sometimes, when the temperature is a little bit high, they multiply rapidly, and when we inoculate other tubes they don't grow any more because they are dead. That is the common laboratory experience with the typhoid bacillus which we constantly cultivate, because it is used daily in the diagnosis of suspected cases of typhoid fever.

Q. Then, Professor, as your experiments are removed from the person or the patient, and as the typhoid fever bacilli is removed from the patient, to that extent those germs become less and less hardy and strong, do they not?

A. A typhoid bacillus is a parasitic organism which will live best upon living beings, living organic material, and it will not live as well on dead organic material as it does in
7524 the living.

Q. And therefore will not live as well on the broth that you use as it will in the human being?

A. It lives only too well. It will multiply at such a tremendous rate, if the temperature is that of human blood, that it will kill itself by producing substances, which are poisonous to itself. If you let a culture grow, the bacilli will die in their own poisons on account of the tremendous increase of them under favorable temperature conditions.

Q. Then, that is a saprophyte, is it not?

A. Well, it has the faculty of growing as a saprophyte, and if you wish to have it described so, we will call it a facultative saprophyte, and not a pure or obligate saprophyte.

Q. Isn't it a fact, Professor, that it is always a saprophyte when taken in connection with laboratory experiments?

A. No, we obtain it from the human being in the laboratory.

Q. But as grown in the laboratory?

A. As grown, yes.

Q. Now, then isn't it a fact that it is only a parasite as applied to the system of man?

A. Yes.

7525 Q. That is the only time in which a typhoid bacillus is a parasite, is when it is getting its work in on the human system?

A. It is a parasite at that time.

Q. And at no other time?

A. At no other time. It is only a parasite at that time, because it never occurs free in nature except when it has come from the intestinal canal of a case of typhoid fever, or from the urine.

Q. Now, Professor, the different cultures of typhoid fever bacilli that are made from the typhoid bacilli coming from various and different human patients have various degrees of hardiness and vitality, have they not?

A. There isn't very much difference in regard to their hardiness. They all grow fairly well on culture media.

Q. But as to the length of life, the longevity as applied to the tests?

A. I think very little is known in regard to that, but I would say that my experience is that there is not so much difference with regard to their longevity. I think that any differences that do occur are mostly due to different compositions of the media upon which they are grown, or are due to
7526 variations of temperature in which they are grown,—surrounding conditions. I don't believe that it occurs from—

Q. Well, I will ask you then if typhoid bacilli coming from the patient, are not more hardy than those that are cultivated in the laboratory?

A. Oh, no, we very frequently find that a parasitic germ will grow much better after it is grown a few times as a facultative saprophyte. It may be more virulent when coming from the patient than it would be in our cultures, but it might grow better and be more hardy perhaps.

Q. But do you not also sometimes find the reverse? In other words, that from your cultures, you don't get as hardy a form as from new cultures?

A. Now, what do you mean by hardy?

Q. I mean longevity and the toughness,—their ability to maintain themselves?

A. Let me have the other question now.

(Question read.)

A. That is right, we find that also.

Q. Professor, you stated that in your experiments the pathogenic bacteria died in five to six days. Under slightly different conditions, might they not live somewhat longer?

A. Under different conditions of temperature and other factors, yes.

7527 Q. You stated that in your experiments the pathogenic bacteria died in five to six days. Under slightly different conditions, might they not live longer?

A. Well, they died in five to six days in the presence of large numbers of saprophytes, at a temperature between ten and twelve degrees centigrade, and if these conditions are changed, if the saprophytes are absent, or the temperature is changed, they will live longer.

Q. So, then, even in the laboratory experiments, the life of the typhoid germ depends largely upon the presence of what you denominate the saprophytic bacteria?

A. Which are in the water.

Q. The presence in the water used on the experiments?

A. It depends upon their presence, yes.

Q. And as you increase or decrease the organic matter which produce these saprophytes, these saprophytic bacteria, you increase and decrease the life of the typhoid bacilli in that experiment, do you not?

A. Yes, sir. Increase of organic material and saprophytes decrease the life of the typhoid bacilli.

Q. So that no laboratory experience can accurately portray the life of the typhoid bacillus under all conditions?

A. Under all conditions?

Q. Yes?

7528 A. I stated last Saturday already that I made the conditions identical, except in one point, that in the laboratory experiments the products of the saprophytes have remained in the culture, or in the water with the typhoid bacilli, whereas in river water they would be diffused; otherwise the experiments that have been made have been made as nearly identical to the conditions existing in the river, as was possible.

Q. How do you know whether or not the oxygen conditions were the same in the samples that you experimented upon as in the river?

A. The typhoid bacillus can grow in the presence or absence of oxygen. It can grow without any oxygen. It is not an obligate aerobe.

Q. But, Professor, would not the absence of oxygen in the sample have a tendency to produce large numbers of your saprophytic bacteria?

A. The oxygen was never absent in my samples; they were cotton stoppered.

Q. Unless you had the same amount at all times, of oxygen in your samples as contained in the river water, would not that condition have a tendency to create a larger number of saprophytic bacteria in your samples than would be created in the water, because of the absence of oxygen in the samples?

7529 A. Why, there was no absence of oxygen in the samples. When I put a cotton stopper into a bottle, the oxygen of the air is present upon that water.

Q. I will ask you, Professor, if you consider the conditions similar with a bottle corked?

A. It is not corked; there is cotton in it, and cotton allows the air to pass in and out, but it does not allow the bacteria to pass in and out. It is a germ filter, but it does not prevent free access of air.

Q. Will you state, Professor, that the same amount of oxygen is always present, passing through the cotton into your sample, that is always present on the surface of the water in the running stream?

A. The amount of oxygen—

Q. And that the water in the sample is continually taking on the same amount of oxygen measured by the quantity of water the same amount of oxygen that is taken on in a running stream,—if you know?

A. The amount of oxygen on the surface of my bottle of water is the same as the amount of oxygen that exists in the air and ought to be the same as that at the surface of the river water.

Q. But is it, and are you sure that it is, and are you sure that the air reaches through the cotton as it does in the water?

7530 A. As it does in the river water. I have no doubt. No means were used to stir up the sample of water which might might occur under certain conditions in the river, mixing more air with the water, and yet we move these bottles about a good deal. I don't know if there is not enough oxygen there under all conditions; certainly, I cannot state any definite figures as to the amount of oxygen in the one and the other case.

Q. In other words you could not tell?

A. The difference, no.

Q. There may be some difference and there may not?

A. Yes.

Q. What is the object of putting the cotton in the bottles?

A. The object is principally to prevent other bacteria from the air to get into the water, and at the same time also to let those which are in the water, not get out. The only object of the cotton is to act as a germ filter; it has no other object.

Q. The object then is to keep the bacteria from the air, from getting in?

A. Yes sir.

Q. But you cannot say that that cotton would not keep the oxygen out to any extent?

7531 A. I am quite certain that that cotton allows the oxygen to pass through, just as well as it allows the gases which may form in the bottle to pass out. That happens also.

Q. You have no way of determining the exact amount of oxygen that goes in that—the comparative amount that goes in with reference to that that is taken up by the water in the river?

A. No.

Q. And just to the extent that the presence of oxygen in the samples of water is limited, a condition is brought about whereby the saprophytic bacteria increase more rapidly than they do in the running stream and therefore the destruction of the typhoid germ is hastened to that extent in the sample?

A. No that is not quite correct because some of these saprophytes can grow very well with little or no oxygen. They are not all strict aerobic bacteria. The strictly aerobic bacteria must have oxygen or they will not multiply. Some bacteria grow best in the presence of oxygen, but can grow also in the absence of oxygen.

Q. Now professor, increased oxygen in the water has a tendency to kill off your saprophytic bacteria, does it not?

A. No, that is not certain. The bacteria which are called obligate aerobic require oxygen for their existence. If you take the oxygen away they will not grow. Oxygen does not act as a germicide at all.

7532 Q. But there is another bacterium present, isn't there that—a bacterial operation in that water that takes place before the aerobe comes in, is there not?

A. Yes.

Q. Now what is that?

A. If there are an-aerobes in that water.

Q. Is the an-aerobic bacteria a saprophyte?

A. An an-aerobe may be a saprophyte or it may be a parasite. An an-aerobe grows only in the absence of oxygen.

Q. Then as you decrease the amount of oxygen you increase the amount of an-aerobic bacteria?

A. That is it.

Q. That is it, isn't it?

A. Yes.

Q. So that the absence of oxygen from a polluted water or water containing organic matter, increases the bacterial content of that water does it?

A. It decreases the growth of the an-aerobes that may be present.

Q. Now then, professor, the life of the typhoid bacilli depends, as I understood you to say, upon the presence of organic matter in the water?

A. Yes, there ought to be some organic matter and a favorable temperature, else it will not multiply.

Q. I will ask you professor, in the analyses which you 7533 have made of the water of the Illinois river, if you know that the same amount of organic matter, or that the organic matter in the samples which you had, remained the same during the whole period of your investigations with reference to determining the life history of—or the longevity of the typhoid germ as it did in the running stream?

A. The lake Michigan water contained not much organic material.

Q. We are talking about the Illinois river water now.

A. The Illinois river water contained more organic material.

Q. But professor, did the samples in which you made the test contain the same amount of organic matter at all times during that test as was contained in the original sample as it came from the water?

A. Of course not, that must have changed.

Q. In other words, the same amount of organic matter and the same kind of organic matter?

A. No, that certainly must have decreased as the saprophytic bacteria multiply. They live upon the organic material and as they multiply they overgrow the typhoid bacillus, and the typhoid bacillus then disappears.

Q. Then the conditions in the laboratory were not the same as those existing in the river at the point where the samples of water were taken?

7534 A. In the river the same condition—

Q. Yes or No, professor?

A. Well, the same condition must exist where there is much organic material in the river, it will be used up by the saprophytic bacteria and if they increase very rapidly the typhoid bacillus will disappear just the same as in the laboratory.

Q. But you stated a moment ago, professor, that the same amount of organic material and the same character of organic matter was not present at all times during the experiment, as was found in the sample at the time it was taken from the river?

A. I stated that the organic material decreased, due to the growth of saprophytic bacteria in the laboratory experiment. I did not state that I had determined at any time the amount of organic matter either before or after the experiment.

Q. That is true. You didn't state that you had determined the amount, but you did say that there was a different amount of organic matter present at all times in the sample, from what was present in the original sample when it came from the water in the river?

A. But I am now only judging from general knowledge, 7535 that if saprophytes grow in a solution of organic material, that they live upon that organic material and if we see an increasing number of saprophytes, we know that they must have multiplied because they have been living upon and using up as food the organic material that is there, so that is a matter of experience and physical laws.

Q. We are speaking now professor, with reference to samples which you examined, and your manner of conducting the experiments with reference to a determination of the longevity of the typhoid germ in that water?

A. Yes.

Q. Now then, you stated the other day I believe, that there was a certain amount of organic matter added in the experiments?

A. Yes, I added some.

Q. And you also stated that that had the effect of producing an additional amount of saprophytic bacteria?

A. No, that I didn't do. I said it was an inappreciable amount that I added, because the amount I added was a platin loopful of a 24 hour bouillon culture, added to four ounces of river water, so in the four ounces of river water a loopful—that is a loop made by turning a small wire around the point
of a pencil, and dropping that into a bouillon culture,
7536 so that the organic matter is what there is in the film of
fluid of this loop, and that is waived through 4 ounces
of the water, so it is only an inappreciable amount of organic matter that I have added to the water. The organic matter I spoke of is that which is already in the water. This decreased in amount when favorable temperatures cause multiplication of saprophytes. I judge that this organic matter decreases because of the great increase in the number of saprophytic bacteria at certain temperatures.

Q. But to the same extent of that organic matter, it has the same effect does it not, upon the experiment?

A. That I have added by a loopful of typhoid bouillon to the 4 ounces of water.

Q. Yes.

A. No, I don't think so; that is imaginary; that is a mere trace.

Q. Well, how about the change that comes over the growth of the saprophytic bacteria? Now that destroys organic matter does it not?

A. Yes, that is the cause, no doubt, of the decrease of organic material in sewage anywhere, and in rivers, as the river flows on.

Q. Now then have you any knowledge, professor, that that decrease was going on in your bottles and in the river in a parallel condition?

A. No, I have already said before that I made no de-
7537 termination of the organic matter there, in the experi-
ments or in the river. Professor Long has determined
the organic matter in the river.

Q. Now professor, are not bacteria extremely sensitive to all changes in foods or to small changes in their foods?

A. Yes, they are.

Q. Now professor, I wish you would explain fully what you mean by the term pathogenic bacteria?

A. Disease producing bacteria.

Q. Is that all there is to it?

A. That is all; disease producing in the animal or in the human being.

Q. I will ask you professor, if you call the colon bacillus pathogenic?

A. That is sometimes virulent and sometimes it is not. That depends upon its virulence. A pathogenic germ may be virulent and may be non-virulent. For instance, the diphtheria bacillus may be virulent, producing diphtheria, and other diphtheria bacilli may not produce diphtheria.

Q. In what way would a colon bacillus produce disease?

A. Colon bacillus would probably not produce disease if it was swallowed, but would do so if it entered the tissues in large numbers from the intestine. It is normally found
7538 in about thirty varieties, in the normal intestine of animals and human beings, and it is perfectly innocent there, but if it should by accident gain access to any of the other tissues of the body it may prove pathogenic. Under such conditions it may or may not prove pathogenic. As to the swallowing of colon bacilli, this is, in my opinion not pathogenic. In fact it has been advocated recently for the treatment of chronic constipation, to drink pure cultures of colon bacilli, so those who believe in that sort of treatment might go to the drainage canal.

Q. Would you recommend that sort of treatment, as a physician?

A. No, I would not.

Q. Professor, can you draw a line of demarkation representing the point when the color bacillus becomes pathogenic?

A. Becomes virulent, you mean?

Q. Yes,—well it is not pathogenic unless it is virulent.

A. It is always considered more or less pathogenic when found anywhere in the body except in the intestine.

Q. You would not under any circumstances then, class it as a saprophyte?

A. It is a facultative saprophyte. It can exist as a saprophyte.

7539 Q. How is that?

A. It is a parasite but has the faculty of existing as a saprophyte so I call it a facultative saprophyte.

Q. Now professor, is there any sharp line between parasites and saprophytes?

A. We find that some organisms appear to be purely parasitic organisms and do not grow at all on dead organic material, so that is an obligate parasite, whereas, we find that a number of the disease producing bacteria can be made to grow on dead organic material, so those can be accustomed to live as saprophytes, that is, on dead organic material.

Q. So, you draw the line of demarkation between the two?

A. Yes, I think we ought to draw the line and we ought to say that there are some bacteria that grow only on living organic material (obligate parasites) and then there are some that live only on dead organic material and are destroyed immediately they are injected into the tissue of man or animal (obligate Saprophytes) and then there are some that stand between those extremes, favoring the living organic material but capable of existing on dead organic material. (Facultative Saprophytes).

Q. Now how is it about the typhoid and the cholera germs with reference to this proposition?

A. The typhoid bacillus is a facultative Saprophyte and 7540 has the faculty of growing on dead organic material. The cholera vibrio the same. Neither one of them, however, occurs in nature and whenever found, it must have come from the intestinal canal of a case which had the disease.

Q. Then each of the two germs is favored in its longevity by the presence of organic material?

A. Both of these germs require for their multiplication organic material. They may live in the absence of all organic material for a short time.

Q. Then professor, if it is true they require organic matter for their multiplication, is it not also true that the proper kind of organic matter as nourishment would have a tendency to increase their longevity?

A. The proper kind of organic materials will produce a better growth.

Q. Then professor, as I understand, you have studied bacterially those bacteria which produce disease?

A. Yes sir.

Q. Have you studied any other waters bacterially for the presence of pathogenic germs than those that you have testified to?

A. I did.

7541 Q. What other waters?

A. Well water of a great many different places.

Q. Any other river water?

A. Yes, I have examined some river waters for Professor Long but I cannot think what they were.

Q. Those were laboratory experiments altogether?

A. Yes all of them. In fact all of my work in this direction has been laboratory work.

Q. Have you studied bacterially any water which has been known to produce disease?

A. Yes sir.

Q. Now will you state what water that is?

A. A number of water specimens received from Professor Long.

Q. Well, what water was that?

A. Well ask him; he can tell you. I am not certain about the places.

Q. You do not know then?

A. I do not know. The question was a question of typhoid infection.

Q. You do not know whether the water came from the Atlantic ocean or the Pacific ocean?

A. I think it came from Rock Island.

Q. But you do not know?

A. I do not know; I have also examined numerous well waters from different parts of the state.

Q. Water that was known to produce disease?

7542 A. Suspected of producing disease.

Q. Did you apply to those waters the same test or a similar test to those which you have testified to?

A. In most of the cases we made plates, growing them in the incubator, and made animal experiments. Water, to which had been added bouillon, was incubated from 24 to 36 hours, and then injected into a Guinea pig, intraperitoneally, usually one cubic centimeter. If these injections proved non-pathogenic to animals, such water was usually considered harmless, but if it proved pathogenic, then other factors had to be considered to determine its dangerous or nondangerous character.

Q. What were the disease germs which you were looking for in those waters?

A. We looked for all pathogenic bacteria.

JUDGE SPRINGER: Are you speaking of this Rock Island experiment?

MR. JEFFRIES: I am speaking of the various examinations he made.

THE WITNESS: We looked for all pathogenic bacteria; that is what we made the plates for.

Q. Professor, suppose that the samples of water that you tested upon the Guinea pigs, with a view of obtaining the effect of that water when injected into Guinea pigs, proved fatal, 7543 would that necessarily mean that the water would be bad as a water supply for the human family?

A. If it proved fatal our test was not considered of much value. The test was only considered of value if the animal did not die inside of several days. When a large quantity of water is supplied with some organic material put into the incubator, the multiplication of pathogenic bacteria is favored, whereas the water bacteria are held back by their growth by the incubator temperature. If injected, the water would have to be very free of disease producing bacteria or the Guinea pig would die. This test is of value only when the animal recovers. It is a very severe test, I realize that.

Q. Professor, I want to ask you if you know whether or not the injection of typhoid bacilli into a Guinea pig will produce death?

A. Yes sir.

Q. Will it under all conditions?

A. If you use enough of it, under all conditions, providing the germ is alive of course, and virulent.

Q. Now is the same true of a colon bacillus if you use enough of it?

A. There is a difference. I don't think the two can be compared.

7544 Q. Well, state it?

A. If you inject bouillon culture of typhoid bacilli you produce no infection of the animal. The animal dies of the poisons of the typhoid bacilli, so it is a toxic effect. The animals cannot get typhoid fever. All animals are immune to typhoid fever, but when you inject the germ of typhoid into an animal, the animal dies of the poisons of the virulent germ. Now, in the colon bacillus, that is quite different. If you inject colon bacilli intraperitoneally, in bouillon culture, in large quantities, you can also kill the animal by the poisons of the colon bacillus, but usually a virulent colon bacillus will cause an infection, and the animal then lives for about five or ten days, then dies with septic peritonitis, that is purulent inflammation of the peritoneum.

Q. Then professor, a water might be perfectly harmless for drinking purposes and yet contain properties that would kill a Guinea pig if injected into it?

A. Yes, that is possible. That is the reason why you attach so little importance to the cases where the animal dies promptly. A water may contain no pathogenic, no disease producing bacteria at all, and yet kill a Guinea pig by the poisonous products of saprophytes produced by some of these germs. These germs themselves do not produce an infection but their products may be poisonous.

7545 Q. What then, professor is the value of that test for ascertaining the condition of the water for drinking purposes?

A. The value of that test is mainly this, that if an animal can live after such a test that it is pretty certain that that water will not be injurious to the person who drinks it. If such a severe test does not have any effect on a Guinea pig, then I think it would be perfectly safe to drink such water from a bacteriological standpoint.

Q. But does that signify that there is or is not pathogenic bacteria present in that water?

A. Pathogenic bacteria in the sense of the colon bacillus might be present in any water.

Q. Well, might not some other pathogenic germs be present?

A. Of course, but it is not virulent then according to the animal experiment. We also plated out this water and looked for pathogenic bacteria. We have always plated out and incubated and examined growing colonies for pathogenic bacteria and perhaps condemned at times a water on the ground of finding pathogenic bacteria there even when the animal did not die.

7546 Q. (Question repeated).

A. I said Yes.

Q. And at the same time there might be no pathogenic germs of any kind of water and yet produce death in the pig, when injected into the pig. That is, I mean pathogenic when taken into the mouth. That is true, isn't it? In other words, as I understood you, you differentiated between pathogenic germs. One might be pathogenic if injected under the skin or into the blood?

A. Pathogenic germs may be virulent and non-virulent I say.

Q. But I understood you to say professor, there might be certain saprophytic production in the water, which when injected under the skin might produce death, but which in fact is not pathogenic, is that right?

A. Yes, that is correct.

Q. Then there can be absolutely no reliance placed upon tests of this character and they mean nothing, do they?

A. Oh yes. I mentioned before that we also made plates and determined pathogenic bacteria from the plates, and secondly, if there are no pathogenic bacteria present, an animal might die anyway of the poisons produced by saprophytes.

7547 Q. Why is it condemned if there are no pathogenic germs in it?

A. Waters which are teeming with saprophytes, usually are found by the chemical test to be very bad. That is the reason.

Q. And that is the only reason?

A. That is the reason, yes. We must judge the potability of a water by three tests, first the physical characteristics of the water may be bad. Now if they are not bad, then the chemical characteristics of the water may be bad, and if both of these are good, then there still may be the third point, the bacteriological character of the water may be such as to condemn it, but the bacteriological character may be good and the others bad. Why, then of course I would condemn it on other grounds than purely bacteriological grounds.

Q. Then it is necessary to have both the chemical side as well as the bacteriological side in this present judgment of the water?

A. All three. I have always insisted on the importance of the bacteriological examination, in cases where neither a physical examination of the water nor a chemical examination reveals any danger. To illustrate: If the water contains only very
7548 few colon bacilli, a test for indol would probably be negative because there were so few colon bacilli there, but in my plates and cultures, I find colon bacilli, so really the bacteriological test is much more sensitive than the chemical test for certain impurities. On the other hand there may not be any pathogenic present although chemical tests reveal other impurities.

Q. Now then professor, going back to these injections into a Guinea pig, I will ask you if you cannot take and in any of these experiments you did not take the bacteria of all kinds, whether pathogenic or non-pathogenic and cultivate them until you had large quantities of that bacteria before the injection was made?

A. No. When you grow that water in the incubator containing the organic material and saprophytes and pathogenic bacteria,—we multiply mostly the pathogenic bacteria.

Q. We are going to eliminate the pathogenic bacteria.

A. If you grow such waters at a low temperature saprophytes will grow better than at a high temperature. At the temperature of the blood the parasitic bacteria grow best; at the temperature of the room the saprophytes grow best. At the temperature of the water, the water bacteria grow best; so it depends upon the temperature as to which one of these classes you will favor in its multiplication. Now, if you
7549 are going to favor the saprophytes, by a low temperature they overgrow the parasites.

Q. You don't understand me, professor. We take a known quantity of water coming from a certain stream. For instance we will take a quantity of water coming from one of those wells that you examined. Now the experiment is being made in your laboratory for the purpose of determining the effect of that water upon a Guinea pig. I mean by that, that you produce a multiplication of the germs contained in that water of all kinds at a temperature of the water in the wells as near as you can.

A. No, we don't do that. Only water bacteria would be favored.

Q. Well then, of what value is the test?

A. The value of the test is in favoring the multiplication of disease producing bacteria. We leave the saprophytes to the chemist. We want to determine simply, are there disease producing organisms present in that water; therefore we favor the growth of the pathogenic bacteria and retard the growth of the saprophytes by growing the water at blood or incubator temperature.

Q. Do you know whether or not all pathogenic germs increase at the same temperature, or require the same temperature?

A. As a rule, all disease producing bacteria have for their optimum temperature, the temperature of the human blood.

7550 Q. Then you use that temperature?

A. Yes sir.

Q. In determining the bacterial contents of the water?

A. We enrich the water in pathogenic bacteria and retard the others by the incubator temperature.

Q. Now, professor, a moment ago we eliminated all pathogenic bacteria from that water. Then you take the water and you must multiply in your experiment the bacteria that is in the water, at what temperature?

A. At 37 degrees which would be the same as blood temperature.

Q. Now you increase the bacteria until you have more in a certain given quantity than really exists in the water?

A. Yes, saprophytes increase some also. There is no question about that. Although the temperature of 37 is unfavorable to the saprophytes. That is the point. It is unfavorable, so they wouldn't multiply very much. Now if the animal dies and we find no bacteria at all in the peritoneal cavity, and it has died very rapidly, we know of course that it has been killed by toxins or poisons that were in that water and yet we may not find in our plates any disease producing bacteria. If there were disease producing bacteria present and they were virulent,

they would multiply more rapidly at 37° C. and overgrow the saprophytes and we could find them in the test. If the animal is infected, we find the germs in the blood of the animal
7551 and in the spleen or in the purulent exudate of the peritoneum in great quantities. In fact that is a common finding in infected animals always, if they do not die right away. If they do die right away we know nothing.

Q. Do you know professor, what the infection was in the water that you examined from these wells, any particular one?

A. Yes, they were mostly proteus and colon. They were mostly saprophytes and colon bacillus.

Q. I mean what was it that caused the water to become suspicious, in other words was it typhoid fever?

A. I don't know.

Q. Have you ever examined the water in any well that has been charged with being infected with typhoid bacillus?

A. Yes sir.

Q. In your examinations of that water did you discover any typhoid bacilli?

A. Never.

Q. Have you in your investigations of any typhoid infected water ever been able to discover in your investigations the typhoid bacillus?

A. I have not except in laboratory experiments when I infected a water with typhoid bacilli.

Q. Professor, is your Guinea pig method one that is actually used by sanitarians in determining the value of water
7552 for domestic purposes?

A. Will you let me add something to my answer to the former question?

Q. Yes.

A. In regard to the finding of typhoid bacilli in supposedly infected wells, I want to add here that I had excellent opportunities at one time. It was in Wisconsin where about sixty cases of typhoid fever occurred in a small hamlet which all seemed to be traced to drinking the water of a certain well, after the arrival in this little hamlet of one person who had been infected with typhoid fever several hundred miles away. In that particular instance it was almost certain that a certain well had been polluted with discharges of this case and was a source of infection in all the cases but at no time was I able to find any typhoid bacilius in this well water.

Q. But from your inability to find them you do not say that they were not in the water?

A. No, I couldn't do that.

Q. You are reasonably certain that the water in that well was typhoid infected?

A. I think we were reasonably certain because people who drank from other wells in the neighborhood were not infected. In one family alone there were six cases of typhoid, two of which died. I reasoned the time of incubation had been sufficient to allow the typhoid bacilli to disappear from the
7553 well water. What became of the typhoid bacilli in this well
water? Why weren't they there any more? If we figure that it takes two weeks to infect, it almost seems as if those weeks had been enough to wipe out the typhoid bacteria that must have been in there, to judge from the whole history of this epidemic. I believe the cause why we did not find the typhoid bacillus is, aside from the difficulty of finding it in small quantities of water, that we never examined that water until the epidemic had already existed for several weeks, and after that time the typhoid bacilli seem to have disappeared. Most of the investigators who examined water in districts where the typhoid infection seems to have been positively traced to the water supply were unable to find them any more.

Q. Now professor, did you examine that water at the time those persons were sick with the fever?

A. Yes, I treated them for six or eight weeks.

Q. Did they cease the use of the water?

A. Yes sir.

Q. Then you cannot measure the appearance or disappearance of typhoid fever germs in that water?

A. When I examined that water, it was several weeks after the epidemic had broken out, probably two or three weeks.

Q. After you had examined it, did you then pronounce to the users of that water that it was good water and that they might then resume the use of it?

7554 A. We condemned the water on suspicion at that time, already before I examined it.

Q. But after you had examined it and failed to find typhoid germs in that water, did you tell those people that they might commence the use of it again?

A. I did not.

Q. Did you not tell them to remove the water from the well?

A. I told them not to use the water.

Q. And they did not.

A. Yes, they did. That is a fact; they did, and it was finally proven that our warnings were not heeded. This epidemic ceased just as quickly as it had come after sixty or eighty cases, I think, had all run their course. It was clearly brought there by one case that came home ill, and everything started from that well. It was such an ideal case for tracing the infection to the drinking water that I was very diligent at that time to find typhoid bacilli in the water.

Q. Now how many tests did you make for the purpose of observing the typhoid bacilli in that water?

A. I plated out probably 250 times.

Q. And found no typhoid bacillus?

A. No, but in some of my cases of typhoid fever, I could
7555 not find them in the excrements either, frequently.

Q. But you do not doubt that they were there?

A. Well, they are at some times but not at all times.

Q. It depends on the stage of the case?

A. It depends on the stage of the case and the number of bacteria in the stools.

Q. And the stage of the disease?

A. There are certain times in the infection when you do find them and at other times you do not.

Q. Did you make Guinea pig tests in those cases?

A. I did not in any of those. They were simply plated out in agar plates; that is all I used at that time, and afterwards I took the suspicious colonies and ran them through to see if I would be able to identify them as typhoid bacilli.

JUDGE SPRINGER: Will you give the name of this place?

A. Little Black, Wisconsin.

Q. What year?

A. Ten or twelve years ago—ten years ago, about.

Q. MR. JEFFRIES: I will ask you professor, which 7556 then is the better test to determine whether or not water is typhoid infected or whether it is infected with disease germs, the bacteriological examination of that water, or the effect of the water upon the persons who use it for drinking and domestic purposes?

A. I think that it is pretty hopeless to examine water for typhoid bacilli.

Q. Then the effect of the water upon the human system is the better test, and in fact is the only test?

A. Upon the human system in regard to typhoid you mean?

Q. Yes, and water-borne diseases?

A. I couldn't make such tests.

Q. Well the experience of the people who use the water for domestic purposes is a better test for the determination of whether or not it contains infected material, disease germs, than any bacterial analyses of the water, is it not?

A. No, the bacteriological examination for disease producing bacteria is the better test.

Q. Then professor, even though you should know that a certain well had had poured into it a certain amount of typhoid infected matter and you had made various bacterial analyses of that water and had been unable to find the presence of typhoid germs in your examination, would you pronounce that water perfectly safe, and would you consider that a far better test 7557 with reference to the sanitary condition of that water, than the effect that that water had upon the people who drank it?

A. I didn't make any such statement anywhere. Now in answer to your last question I will have to say again that the bacteriological test is only one of the tests employed in judging a water; and I do not want to be understood as urging a bacteriological test alone as to the potability of water. I want to be understood as saying that it is a most valuable test to determine the disease producing bacteria present in water. I have stated also the difficulty of finding typhoid bacilli at times of epidemics in suspected water supplies.

Q. Professor, we have a certain well. You are called upon to determine the sanitary condition of the water in that well.

A. I wouldn't determine it by a bacteriological examination alone.

Q. With reference to whether or not it contains disease germs of any character. You are told that bacterial investigations have been accurately made, or as accurately as the science of bacteriology can make them, limited in number of course. You are also told that from the use of the water by the people, it has produced certain effects. In other words the effect of the water upon the human system when taken into it and the result of the
bacterial analyses are not disclosed to you at all, and you
7558 are asked the question, Which do you prefer in order to
pass judgment upon that water. We do not propose to give you the opportunity to use both, but which of the two means is the better and which of the two would you call for, the effect of the water upon the human system of those who drink it, or the result of the bacterial analysis standing alone, the two standing alone?

A. I wouldn't pass my opinion on one point alone. I would want in a case like that, where I was to decide as to the sanitary question of water being used, not to pass any opinion as to the potability of the water unless I had all the data, physical, chemical and bacteriological, and if those were lacking why I might prohibit the use of the water on general suspicion.

Q. Then professor, you do not consider the fact that a certain water producing the typhoid disease when used for domestic purposes and that fact alone as being sufficient to condemn a water that is used in that way?

JUDGE SPRINGER: I object to the question because he has stated specifically that he would condemn it on suspicion.

A. Yes sir, I did that.

Q. MR. JEFFRIES: Now then, which of the two tests, the bacterial test or the actual results, or the actual experience
of the people who drink the water, is the better?
7559 A. If I knew that a certain water was exposed to all
sorts of pollutions, even if a complete purification of those pollutions took place again, conditions as they exist in rivers generally, with continuous and repeated pollutions by all sources, and in such river water, I didn't find bacteriologically, chemically or physically, evidences of disease, I would still prohibit

that water, but I think I would prohibit that water on general suspicion, as not fit to be used as drinking water because every river is exposed to continual pollutions, even if no sewage at all enters it. River water used for domestic purposes should always be filtered.

Q. Professor, let us eliminate all physical conditions. Let us eliminate everything except the water itself contained in a well for instance and you are told that the water is typhoid infected because the people who drink it were made sick of typhoid fever, would you consider it necessary to call upon a bacteriological analysis of the water before you condemned it?

A. No sir, that is just the point and the reason for my former statement. I would condemn the water on the experience you mention, just the same as I would condemn any river water that was not filtered, for the use of any city, even
7560 if it had not received sewage.

Q. We are talking about water in a well now.

A. The conditions are the same with regard to condemnation of a water on suspicion.

Q. Suppose you are called upon to pass an opinion upon the sanitary condition of a water in a well, what is the first question or the first condition that you inquire into?

A. I think I have stated before that I would not undertake to decide the sanitary condition and potability of the water on bacteriological examination alone.

Q. I am not talking about the potability of the water, but as to the quality of the water?

A. I would have nothing to do with such an investigation except the bacteriological side of it.

Q. I want to see how far you rely and how much confidence you have in the bacterial analysis of water?

A. I think I can easily answer that.

Q. I want to know whether or not you would put more reliance upon your bacterial analysis of the water than you would upon the effect of the wa[illegible] upon the people who drank it, if its effects were known?

A. I think that if I was able to make such a test, an animal test, as I have described, with that water, without producing any effects upon the animal, whatever, I think that I would be willing to drink that water.

7561 Q. You have not answered that question, professor?

A. That is not excluding even the presence of small numbers of typhoid bacilli in that water.

Q. Now professor, I am confining you to two tests, one the experience of the people who use the water and the other your bacteriological examination of that water, which of the two would you place the more reliance on, the bacteriological analysis of the water or the experience of the people who drank it?

A. What do you mean by the experience of the people who drank it?

Q. Well the experience with reference to the condition of disease.

A. That may be all imagination on the part of the people who drink it. That may be pure imagination. People frequently attribute various affections to water, and it is usually something entirely different which has made them sick. They always imagine when they go from one place to another and eat and drink all sorts of things that it is the change of water that has made them sick. You hear that constantly.

Q. Supposing, though, professor, it should be determined by persons capable of making an examination that the water from the well was the cause of typhoid fever and that the typhoid fever was the experience of the people in drinking
7562 the water, which of the two tests would you consider the most reliable?

JUDGE SPRINGER: I object to the question.

A. If it had been the supposed experience, even the suspicion that the water was the cause of an epidemic I would prohibit the use of that water on suspicion.

Q. Then that would be the better test, the experience.

A. That is no test. It is only a safeguard against suspected danger.

Q. Now you stated a moment ago that if you had examined the water of the well about which we spoke and had tried the guinea pig test and found that it produced no bad results,in other words did not produce the death of the pig, that you would have pronounced the water good?

A. No symptoms of any infection, no elevated temperature, no decrease of weight in the animal, yes.

Q. Now might not those experiments have been made and the water contain typhoid germs, and yet no serious results have been produced upon the pig?

A. Yes but then they would be present in very small number. You refer now to the fact that I use only comparatively little water, and, therefore, would inject but few typhoid bacilli whigh might not produce the death of the guinea pig, and yet there would have been typhoid bacilli in the water. Now if they are so much diluted and in such small numbers 7563 as that, I have some serious doubt whether they could in fact produce a direct infection by drinking such water. It is my opinion that they would not produce infection. I have stated in this testimony that I did not believe in the direct infection by water as much as in the indirect infection by polluted water containing very few typhoid bacilli, reaching and multiplying upon favorable culture media, and this culture media, vegetables, milk, etc., being swallowed by the patient who then becomes infected.

Q. Professor, take this well in Wisconsin which you examined?

A. If I had examined the milk in that case I might have found something, but I didn't.

Q. I understood you to say that you felt reasonably certain that the typhoid fever came from the well?

A. At that time, yes.

Q. Now assuming that it did come from the well, cutting out all possibility. making the assumption that it did come from the well, are you reasonably certain if you had applied your tests of that water upon Guinea pigs, that it would have produced death?

A. I am certain it would not have produced death by typhoid toxin.

Q. Because you did not find typhoid in it?

A. Yes.

ADJOURNED until 2.00 P. M., same day, Oct. 5, 1903.

2:00 P. M., Monday, October 5th, 1903.

7564 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination by Mr. Jeffries and testified as follows:

Q. Professor, do you know whether or not it is a fact that cities using water containing small amounts of sewage have higher death rates from certain causes than cities using water containing no sewage?

A. I think that is true. Intestinal diseases particularly. That is when unfiltered water is used.

Q. Now then, do you know whether or not it is a fact that cities using water of much sewage have higher death rates from certain diseases than other cities using water containing smaller amounts of sewage?

A. I should judge that that is the case. Intestinal diseases particularly, where unfiltered river water is used will be more numerous when there is much fresh sewage entering it at a place shortly above the intake.

7565 Q. Professor, what do you say as to the hygienic effect of the organic matter contained in the Chicago sewage?

A. The hygienic effect?

Q. Yes?

A. It is no doubt there, and the Chicago sewage should not be drank. I don't know if I understood your question, Mr. Jeffries?

Q. I think you do. In other words, what do you say as to the hygienic effect of the organic matter contained in the Chicago sewage?

A. What do you mean by hygienic effect?

Q. Well, supposing it is to be used for drinking purposes?

JUDGE SPRINGER: Have on the health of the people drinking it you mean?

Q. MR. JEFFDIES: Hygienic effect?

A. I should judge that if there was so much organic matter in the water, there also would be large quantities of saprophytic organisms, which could produce substances that bring about intestinal diseases ,aside from any pathogenic bacteria.

Q. Aside from the presence of pathogenic germs?

A. Yes.

Q. Yes. Now then, professor, does this organic matter
7566 in distinction from the organisms which accompany it, have any qualities which make it injurious to health?

A. I would leave that to the sanitarian and to the chemist to decide.

Q. Suppose, professor, that the chemist should say that there were certain living organisms accompanying the organic matter, certain living organisms the nature of which he could not tell, accompanying these organic matters down the waters of the river, is there anything in bacteriology that would determine the character of those organisms as to whether they were pathogenic or non-pathogenic?

A. Yes. I could determine whether they were pathogenic or non-pathogenic.

Q. That is on condition that you could make an analysis that would directly portray the condition of those organisms throughout the whole year?

A. Yes, although also my individual sample might prove to contain such pathogenic bacteria.

Q. And it might contain pathogenic germs, and yet they not be detected, might it not?

A. If the pathogenic germs would be greatly diluted, they could escape detection.

7567 Q. And there might be a great many pathogenic germs contained in those living organisms following the organic matter which even could not be detected from a bacteriological examination of the water?

A. No, if there is much organic matter there would be much saprophytic life there. The saprophytic bacteria would increase at such a tremendous rate that the other bacteria which produce disease, the pathogenic bacteria, would be overgrown,—not that there is a lack of food supply for them, but they are simply overgrown, annihilated by the great increase of other bacteria which are found to multiply in that organic matter.

Q. Now what do mean, professor, by the term "overgrowth of the saprophytic bacteria?"

A. They would increase at the temperature of water much more rapidly than the pathogenic bacteria, which would not multiply at all at the temperature of the water, while pathogenic germs need not be directly killed, they would certainly not multiply at the temperature of water, whereas, the other saprophytic and water bacteria would multiply and they would increase in the presence of organic matter at such a tremendous rate that they would overgrow the pathogenic bacteria. To illustrate: If we take grass seeds and we take the seed of one tropical and
delicate plant, which can only grow in a different climate
7568 under a different temperature, and you sow them all out
together, the conditions of temperature will be favorable to the grass seeds, and they will be growing up rapidly and exterminate by their overgrowth the more delicate plant or flower. So it is with disease producing bacteria, when they are mixed with saprophytes or when they are mixed with water bacteria and exposed to a temperature unfavorable to the growth of disease producing germs, but very favorable for the rapid multiplication of saprophytes whose dense growth make life and existence impossible for the disease producing germ. In my opinion that is the most important cause of the disappearance of pathogenic bacteria, even in laboratory experiments. We see the same competition of micro-organisms in the laboratory daily, when we sow out a mixture of three or four germs and the conditions of temperature for one are more favorable than for the other. Some will be wiped out by others for which the temperature is more favorable. The same occurs in water into which equal quantities of germs have been inoculated. When this water is plated out, some of them will grow so thickly as not to allow the others to appear at all, yet we know they have been alive and know they were there, and yet they cannot grow. They disappear.

Q. Now eliminating the large quantities of organic matter
from the water and assuming that there is only a small
7569 quantity of organic matter in the water, that does not
necessarily imply that there are no living pathogenic bacteria in that water, does it?

A. No, in fact that would rather favor their persistence there. The less organic material, the less saprophytic life, the longer the pathogenic germs are capable of existing there, even if they can not multiply on account of the low temperature of water. If there are but few other bacteria present, pathogenic germs will live longer and it will take a longer time before they are destroyed than if there were billions and billions of the saprophytes, making it impossible for pathogenic germs to exist.

Q. What then, professor, in your opinion is the active principal of water that is not wholesome?

A. Bacteriologically speaking, it is the presence of disease producing micro-organisms, or even the presence of saprophytic bacteria in great number.

Q. Now then, state plainly again how the presence of both characters of bacteria which you have just mentioned, produce disease. In other words, the pathogenic bacteria and the saprophytic bacteria?

A. If pathogenic bacteria are in the water and have not died there yet, they will be distributed and separated more
7570 or less by dilution, according to the different conditions
existing for dilution and then require mostly, for their pathogenic effect, of first meeting with a favorable temperature, and favorable culture media, before they produce an infection. If a very pure water and a very potable water is infected with pathogenic bacteria, a water tolerably free from organic material they would live longer than in a badly polluted water with much organic material. Now, even under the latter conditions there would be a large separation by dilution, which is probably the reason why we do not find them, so they would be separated so far apart from each other that in order to produce an infection it would be necessary that they should first meet conditions favorable for multiplication. Take the case of the typhoid bacillus, one germ might be in a barrel of water and if that one germ happened to get into a milk can, during a hot summer day, for 24 hours perhaps, this bacillus would find in the milk a favorable culture medium, and the persons drinking that milk would drink a culture of typhoid bacilli; whereas, one would have to drink all that water to get one baccillus, and further one germ alone would not produce an infection. Numbers are

very essential to produce an infection. In order to produce typhoid fever the germ must be swallowed, it must be virulent; it must be swallowed in great enough numbers, and even 7571 then the resistent forces of the organism must be decreased. We see occasionally, where the infection has been traced to milk, that some people partaking of it develop typhoid fever and others do not.

Q. Now professor, in view of what you have just stated, I will ask you what effect, aside from dilution, that the discharge of 250,000 cubic feet of water per minute through the main drainage canal, has had upon the sewage of Chicago, assuming that prior to the opening of the canal the diluted substances containing the sewage of Chicago passed through the canal at the rate of 35,000 cubic feet per minute, and that the discharge in both instances passes down the Illinos river. Do you understand the question?

A. Yes. I think so. That is very hard to answer. I should judge that the less the dilution the more rapid will be the multiplication of saprophytes, and the destruction of the organic material but the greater the dilution the slower will be the destruction of organic material by saprophytes. In other words, if you have much organic material, you favor the growth 7572 of great quantities of saprophytes, and they dispose of the organic material more rapidly than if you spread them over large areas and allow the saprophytes to attack it there.

Q. State professor, what difference there would be in the longevity of pathogenic germs, or disease producing germs in those two streams of water which I have just mentioned?

A. I have no data as to that and this would be merely speculative, if I wanted to compare that. I will however, in a general way try to answer you.

Q. That is what I want

A. I will say what I have said several times, that the more organic material there is, the more rapid the destruction of the pathogenic bacteria, so the dilution of the organic material does not increase the rapidity of destruction of pathogenic bacteria. In fact it would rather tend to decrease it. If we place pathogenic bacteria in sterilized water, where no other bacteria are present, they live longer than if we put them into the worst sewage contaminated water. The purer the water the longer the life of the pathogenic germ. By purer I mean less organic matter, therefore less saprophytes.

Q. So that with two streams flowing side by side, carrying the sewage from the city of Chicago, or three-fourths of the sewage from the city of Chicago, with a population of 1,600,000 people, the one existing in a diluted condition with the
7573 flow limited to 250,000 cubic feet of water per minute; the
other stream limited to a flow of 35,000 cubic feet per minute, if I understand you, you say that the disease producing germs will disappear much more rapidly in the smaller stream than in the larger?

A. Yes sir.

By agreement of counsel witness Professor F. Robert Zeit is temporarily withdrawn from the stand, and witness Wm. S. Sayer is permitted to testify at this time in view of the fact that he is about to leave the city and will be absent for three months.

7574

WILLIAM S. SAYER,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer and testified as follows:

Q. State your name, residence and occupation?

A. My name is William S. Sayer.

Q. Your residence?

A. My present residence is 619 West 66th Street.

Q. Chicago?

A. Chicago.

Q. What is your occupation?

A. I am employed by the Kennicott Water Softener Company.

Q. Where were you educated?

A. I took my college course at Beloit College.

Q. How long were you there?

A. Four years.

Q. After your college course did you attend any other university?

A. I attended the University of Chicago.

Q. How long?

A. I begun the first of January, 1900, and was there until the beginning of this work.

7575 Q. Beginning of this work here; what was that date?

A. October 1st, 1901.

Q. Nearly two years?

A. Yes.

Q. What was the nature of your studies at the University of Chicago?

A. My work was chemistry and bacteriology.

Q. State what amount of bacteriological work you performed, if any, during that period?

A. Well, my work covered all of the courses given in the non-pathogenic and pathogenic bacteriology, under Dr. Jordan and Dr. Davis and others connected with that department.

Q. Did that include the asecrtainment of the number of bacteria in given quantities of water?

A. It did.

Q. Were you able to by that instruction, to make such ascertainments?

A. I was.

Q. State whether you received any instructions from anyone in the latter part of 1901, to make certain bacteriological examinations of water, and if so, where?

A. I was instructed by Dr. Jordan under the direction of Mr. Irons, to go to Grafton, and proceed with this work.

Q. Well, what did you do at Grafton?

7576 A. We established a laboratory at Grafton, and during the period from October 1st until about the 25th of December, we made daily analyses of the water, bacteriological analyses of the water of the Mississippi river, of the Illinois river—

Q. From what points were those samples taken that you analyzed or examined?

A. The sample from the Illinois river was taken about three miles, I think, from the mouth of the Illinois river.

Q. Was it above any possible mixing of the waters of the Mississippi river water?

A. It was.

Q. And where were the others taken?

A. The Mississippi samples were for the most part taken near the government dyke, near the mouth of the Illinois river.

Q. How far above the mouth of the Illinois river was that?

A. It was very near the government dyke, but the Mississippi river is some eight or ten inches higher than the Illinois river, so that there was no possible means of contamination or mixing.

Q. Who took the samples from the water?

A. Mr. B. F. Robinson, took most of these samples.

Q. Were you with him at the time?

A. I was with him most of the time during the first two
7577 months and once or twice a week during the last month.

Q. And what did you see so far as what was being done by Mr. Robinson, and yourself, in regard to the taking of the samples, what method did you pursue?

A. We took all samples in bottles which had been previously sterilized by subjecting to a temperature of 170 degrees, dry temperature—

Q. Fahrenheit?

A. Centigrade. And these bottles, after sterilization, were used for the taking of the samples.

Q. How many samples did you take each day?

A. One sample from each of the two rivers.

Q. Each day during this period?

A. Yes, Sundays excepted.

Q. From what part of the stream did you take them?

A. We took the Illinois from mid-stream, and the Mississippi perhaps a little bit to one side, but it was near the center of the current.

Q. How far down below the surface did you get the water?

A. About six or eight inches.

Q. What kind of an instrument did you use for that purpose?

A. These samples were taken by hand.

7578 Q. What did you do when you took the samples out of the water, what did you do with them?

A. They were taken to the laboratory as soon as possible, in order to make the detrmination within the hour. These determinations were all made with very few exceptions, within an hour of the time of taking.

Q. Now what was the nature of the determinations that you made of those samples?

A. The principal determination was a count, an enumeration of the bacteria developed on gelatin plates.

Q. Had you had sufficient experience in developing numerical bacteria upon gelatin plates to ascertain accurately the presence of bacteria in the samples that you examined?

MR. JEFFRIES: That is objected to. Let him state his qualifications.

A. I think Dr. Jordan perhaps will answer for that.

Q. Well you did make them in that way?

A. Yes sir.

Q. During nearly two years time that you were with Professor Jordan, did any of your work cover this kind of ascertainment?

A. It did.

Q. How much of it?

7579 A. Why simply in the course, we make the routine examination of waters and then take a period of some months, I was working in Dr. Jordan's laboratory under Mr. Irons; before this period I worked in Dr. Jordan's laboratory as an assistant.

Q. MR. JEFFRIES: With whom?

A. Mr. Irons.

MR. DRENNAN: How long as an assistant?

A. I think it was two months, I am not certain.

Q. JUDGE SPRINGER: Well, how did you record, if at all, the results of your examinations?

A. We were furnished blanks which have been submitted, and all of the results were submitted on these blanks, printed blanks.

Q. I will hand you this paper, and you may state whether that is ones of the blanks and whether the others were of the same character, which were furnished you?

A. This is one of my blanks, with my signature.

Q. Just explain now, generally, what this blank provided for, and what you did in order to fill it up?

A. The blank provides for the date, the number of the sample, source of water, hour of collection, hour of examination, temperature of the water; temperature of the air; the amount of dilution, the number of bacteria per cubic centimeter, and other remarks. Some of these I believe contain additional information. 7580

MR. JEFFRIES: Let me look at that sheet.

THE WITNESS: Some of the later sheets contain more information I believe, than that. That was the first week's work.

JUDGE SPRINGER: I hand you also several other blanks of the same kind, numbering in all I believe, 18. State whether those are the blanks that you received, and whether the writing on these blanks was entered upon them by you?

A. These were the blanks furnished to me and this is my work.

Q. You did that writing yourself?

A. I did.

Q. State whether the tables which I have shown you contain a correct statement of the facts purporting to be recorded in them?

A. This work is correct so far as we were able to determine.

Q. And these tables are correct ascertainments of the results which you obtained in the examinations which you made during that period?

A. Yes, as near as could be made. You will find duplicate sheets for part of them.

Q. Professor Jordan has them?

A. The first sheet here for Mississippi and Illinois river, I believe, and the later sheets give the Illinois on one sheet and the Mississippi on another.

7581 Q. Those are the originals?

A. These I believe to be the originals.

MR. JEFFRIES: I want to know which refer to the Illinois river, which refer to the Missouri river and which refer to both.

JUDGE SPRINGER: They are right here on the face of it, Illinois river at Grafton, and the Mississippi river at Grafton.

Q. State whether each sheet contains the result of your examinations of the water of the Illinois at Grafton, at the points you have indicated before, and the Mississippi river at Grafton, on the dates stated therein?

A. I don't want to put this down for evidence. I think you mean—

Q. I want to know whether this sheet has on it both the Mississippi and the Illinois rivers at Grafton?

A. Some of the sheets have both; some of the sheets are made out for the Illinois exclusively and some for the Mississippi exclusively.

Q. Is that fact stated on the sheets themselves?

A. It is.

MR. JEFFRIES: If one set of sheets contain the whole information what is the use of putting all in?

MR. DRENNAN: They do not.

7582 THE WITNESS: There is no duplication here, I believe.

JUDGE SPRINGER: It requires all of these sheets to correctly set forth all the bacteriological examinations that you made?

A. I believe it does.

Q. And they do contain all, do they that you made during that period?

A. So far as regards enumeration, they do.

Q. Was there any determination made under what is known as the fermentation test?

A. There was.

Q. What did you do with those sheets?

A. I turned all of those sheets into Dr. Jordan.

Q. And when those sheets shall be presented by him with your signature, as it is here they would contain the fermentation tests that you made at that time?

A. They would.

MR. JEFFRIES: I object to the question for the reason that the witness cannot tell now what they contain, since they passed out of his hands.

Q. JUDGE SPRINGER: Have you indicated upon these plates the facts which are called for in the blank at the head of each of these columns, as for instance, source of the water

and the date of collection and so on, temperature and
7583 so on?

A. The blanks have been to a certain extent modified to suit the work as it was carried out.

Q. To correspond with the facts?

A. Well, to correspond with the method of work. These blanks were not exactly suited to our work.

Q. The blank was not exactly suitable, but you have corrected it so it does correspond?

A. Yes sir.

Q. So that these sheets then do show all of the facts as stated on them, according to the manner of our ascertaining them?

A. I believe they do.

JUDGE SPRINGER: I want it understood that he may read them in evidence, each one of them, or it may be considered as having been read in evidence. I want to put these in evidence. I don't want them offered for identification, because they are evidence; they are the original plates; they prove what they are on the back of them, and I want the record to show that they are read in evidence.

MR. JEFFRIES: I object to the reading of the tables into the record or to their being introduced as exhibits for the reason that the proper foundation has not been laid so as to constitute evidence upon any of the issues involved in this
7584 case.

JUDGE SPRINGER: The record will show that the witness read these sheets, beginning with 1 to the end, and they are as follows:

(It is this 3rd day of December, 1903, agreed by counsel that these sheets shall be marked by the Commissioner Defendants' Exhibit F, for identification sheets 1 to 18, and that witnesses may hereafter draw conclusions from these records as if they were here set out in extenso, but that said exhibits need not be printed.

JAMES TODD,
Counsel Sanitary District.
H. CREA,
Representing State of Illinois.
SAM. B. JEFFRIES,
Ass't Att'y-Gen., State of Mo.)

7585 MR. JEFFRIES: I object for the reasons before stated, to their being read in evidence.

CROSS-EXAMINATION.

By Mr. Jeffries.

Q. What is your name?

A. William S. Sayer.

Q. Are you connected with Professor Jordan now in any way?

A. I am not.

Q. How long has it been since you have been working for him?

A. I have not worked for him since the close of this work, in January, 1902, although I worked under him for six months after that, that is doing the bacteriological work.

Q. What was your relation to Mr. Irons?

A. Mr. Irons visited the laboratory at Grafton periodically, while I was there. I had charge of the laboratory and he inspected the laboratory about once a week.

Q. You did not collect all the samples of water yourself?

A. I did not.

Q. What was your relation to Professor Jordan at that time?

A. All of my work was done under Professor Jordan's direction.

7586 Q. How many assistants did you have?

A. One.

Q. Did he assist you all the time; was he there with you all the time?

A. After the first month he was with me all the time.

Q. Now how long was he with you?

A. About two months · approximately. I don't know whether I quite understood your last question. He helped me all the time, but he gave his entire time for the first part of the period.

Q. Who was that?

A. Mr. B. F. Robinson.

Q. Did you ever go off and leave Mr. Robinson in charge?

A. No sir.

Q. You were there with him all the time?

A. I was there whenever there was any work done, all of the time.

Q. State again the time of the year that these samples were taken?

A. These samples were taken beginning with October 1st, and continuing then for nearly three months.

Q. Do you know the exact date that the last sample was taken?

A. I am not positive; I believe it to have been December 24th.

Q. December 24th?

7587 A. December 24th.

Q. Was it not December 20th?

A. As I have said, I am not positive, but I believe it to have been the day before Christmas.

Q. Well, you were ordered to stop at that time, were you not, by Professor Jordan?

A. We were ordered to stop at about that time.

Q. What was the stage apparently of the water in the Illinois river during that time; it ran practically the same did it not during the whole time?

A. You mean the water level?

Q. Yes.

A. The river was rather low as will be shown by my reports.

Q. During the whole time?

A. During nearly all of the time, excepting the first part of the period. I cannot state how long.

RE-DIRECT-EXAMINATION,

By Judge Springer.

Q. I believe you stated that you were personally cognizant of the fact that these samples came from the places indicated on this blank?

A. I saw most of the samples taken and this would itself
7588 show whether the others were taken similarly.

Q. And those that you didn't take personally were handed to you by the person that did take them?

A. They were.

Q. Mr. Robinson?

A. Mr. Robinson.

Q. I believe you stated that within an hour after you had taken them you had plated them on this—

MR. JEFFRIES: Objected to as leading.

I move to strike out the tables so read in evidence for the reason that the proper foundation has not been laid for their introduction as would make any evidence in this case.

MR. DRENNAN: We think the foundation sufficient, so we will stand by them.

It is hereby stipulated and agreed between counsel for both parties, that the witness Mr. William S. Sayer shall not be required to sign his testimony, but that the same shall be examined by the Commissioner, and the Commissioner shall be permitted to make any corrections that may be necessary to correspond with the testimony as given by the witness, such as typographical errors, and the evidence when so corrected and certified by the Commissioner shall be read and considered in evidence the same as though signed by the witness.

7589 Professor Zeit resumed the stand for further cross-examination by Mr. Jeffries.

Q. Assuming professor, that all the sewage of the city of Chicago was discharged into the Illinois river in a diluted condition, or in a diluted state of sewage and water amounting to a flow of 35,00 cubic feet per minute, what effect would the addition of 250,000 cubic feet of water per minute have upon the life and longevity of disease producing bacteria contained in the sewage of Chicago?

JUDGE SPRINGER: I object to this question upon the ground that it doesn't state the point in the Illinois river at which this assumed sewage of Chicago is emptied into the Illinois river, and further that it does not state the place at which the dilution was added to the sewage content.

A. I think I have answered that in a general way before.

Q. No, not in the way the question is put.

A. The greater the dilution the longer the life of pathogenic bacteria, but as to the possibility of infections, the greater the dilution the less the possibility for direct infection, on account of the greater dilution. If you turn a thousand typhoid

bacilli from a case of typhoid fever into a badly polluted stream with very much sewage, then they will die sooner, than if you pour a thousand bacilli into a stream that does not have sewage otherwise, except from the discharge of the typhoid fever
patient. The more water, the greater the dilution; the
7590 further will be separated the individual bacilli and, there-
fore, also the less the danger of direct infection by the typhoid bacilli, on account of the smaller number.

Q. But what effect has that upon the life of the typhoid germ, the disease producing germ; that is the question?

A. I gave that. It will live longer when there is no sewage than where there is sewage.

Q. Then professor, with the additional flow of water, the disease producing germs will flow much longer in the water than they will in a lesser volume of water?

MR. DRENNAN: I object to the question because it does not specify the character of the water.

MR. JEFFRIES: Under the hypotheses first stated, assuming that the sewage of Chicago went through two streams, one with a capacity of 35,000 cubic feet per minute; the other stream at the capacity of, and at the rate of 250,000 cubic feet per minute—

MR. DRENNAN: I object to the question unless it is specified that it is the quality of water that flows in the streams, the drainage canal and the Illinois river.

MR. JEFFRIES: What do you mean by quality?

MR. DRENNAN: The same water.

MR. JEFFRIES: I don't care whether it is the same kind
of water or not. I presume counsel for defendants do not
7591 take the position that Chicago emits 35,000 cubic feet
per minute of pure sewage?

MR. DRENNAN: No, we don't admit that.

Q. (Question repeated).

A. A typhoid bacillus will live longer in a water not seriously polluted by sewage, than in another water that is seriously polluted by sewage.

Q. Then in this particular instance that I have mentioned, the typhoid germs and the disease producing germs will live much longer in the one containing the larger flow, will they not?

A. The one having the greatest dilution; it will.

Q. Well, which one would have the greatest dilution?

A. The one that receives the most water.

Q. The one that had a flow of 250,000, or the one that had the 35,000 flow?

A. Well, the one with the 250,000.

Q. Now professor, would not the addition then of 215,000 cubic feet per minute, have some effect upon the zone of purification in the river?

A. You are asking me again questions on sanitation,
7592 not purely bacteriological questions. A river water of
sufficient quantity to dilute the sewage water fifteen times with a flow of at least six-tenths meter per second permits sedimentation banks of sewage to be formed. No putrefaction or stench forms, which, however, is the case in the drainage canal, no algae or fishes are destroyed, which is the case in the drainage canal. The chemical impurities becomes insignificant as the dilution becomes greater than the ratio given and the bacterial impurities, of course, remain longer, but also disappear in what I have been terming here, the purification zone.

Q. In other words, they disappear in the quantity of bacteria contained in the known volume of that water?

A. We cannot find them any more.

Q. Now do I understand you to take this position, professor, that the sanitary condition of a water does not necessarily mean that water is free from disease-producing germs, but that they have been so distributed by dilution, as to disenable the bacteriologists to discover them in his analyses of that water?

A. Yes, that is true.

Q. That is your position, is it?

7593 A. For a certain length of time, as I have mentioned be-
fore, and as seen in my experiments. I believe that typhoid bacilli can exist in a slightly polluted water for some time.

Q. And just as the other bacteria decreases the ability of the typhoid germ to live, increases?

A. No, that would not be quite correct. If in a water which has been badly polluted by sewage and pathogenic germs, the saprophytic bacteria decreases again, the typhoid bacilli, must have already disappeared before. The pathogenic bacteria disappear sooner than the saprophytes.

Q. That, professor, is taking the sewage in its original state and without adding to it at any time any other substance, diluting substance, is it not?

A. That is taking the river water, contaminated with various organic material.

Q. And as the saprophytic bacteria disappear by dilution or what not, it renders the water more favorable to the life of the typhoid germ?

A. Mr. Jeffries, you mean that after the sewage had been deposited in the river, or do you now speak of a primarily pure water which is infected with typhoid bacilli only.

Q. I am speaking now professor, not of the sewage in its original condition, but I am speaking of the sewage being
7594 discharged into a volume of water which prior or formerly
was less than now. If the conditions conducive and favorable to the life of the typhoid germ, are not greater under the added volume of water than formerly?

A. Yes, because the dilution of the organic material is greater.

Q. Then professor, as you add the volume of water you increase the rapidity of the flow, you increase the abilities of life of the typhoid and other pathogenic germs. Now as you increase the ability of life, and as you increase the ability to flow, do you not at the same time change this zone of purification that you spoke about a few days ago?

A. Yes sir, you change the zone of purification if you do that.

Q. Push the zone on farther down to the mouth of the river, do you not?

A. Yes sir.

Q. Now professor, taking the conditions as they exist with an added flow of 250,000 cubic feet of lake water per minute, from Lake Michigan, which is disease-laden, pure lake water or what-not, this additional flow added to the Illinois river when the combined discharge of the sewage and diluting

7595 substance, prior to the opening of the canal was only 35,000 cubic feet per minute, as testified to by Professor Long—assuming those conditions I will ask you if it is not a fact that the disease producing germs would live longer and swim farther or flow farther down the river since the opening of the canal than they would prior to the opening of the canal?

A. From my own investigation of the matter, I look upon the drainage canal as one big sewage tank, even as it is now, with an increased amount of water, and I hardly believe that very much will get out of the drainage canal in the way of pathogenic bacteria, alive, because the conditions are certainly such as to show no lack there of organic material and no lack of saprophytic life.

Q. Do you know that they will not get out?

A. No, I do not know. I only argue now from the results of my experiments in the laboratory.

Q. If it be a fact professor, that they would not get out in the short length of the drainage canal, why is it that all these improvements have been going on in the last few years in this country, to correct the sanitary conditions of the water supply?

A. Oh there is no question that there are many causes for objection to turning sewage into a river. At the place where sewage enters it, there must be, no doubt, many physical
7596 characters about this water to make it objectiona[illegible], to
make it a nuisance. Alone for the nuisance, it would be essential not to turn sewage into river waters, and if most of the cities now turn only the effluent of sewage into a river water, it is simply to remove the nuisance, but also the effluent of sewage has been known to contain micro-organisms which were injurious, but that was not as objectionable to the senses as when sewage itself is turned into the water.

Q. Do you know how they treat this sewage?

A. Yes, in a general way.

Q. Isn't the ability and the facilities for removing the objectionable matter from the sewage in these plants far more favorable than the water now contained in the drainage canal?

A. To prevent the pollution of the river?

Q. Yes.

A. There is no question about that.

Q. Then, professor, if it is possible for some disease germs to escape these plants, and get into the water, why can you make the assertion that no objectionable material will pass out of the canal, that is no objectionable disease producing substances will pass out of the canal.

A. I did not say pathogenic bacteria in the effluent; I
7597 said objectionable substances. Such objectionable substances may be for instance, the products of saprophytic bacteria; they pollute the river just the same.

Q. Now I will ask you professor, if they are less or more objectionable than the substances that pass out of the drainage canal?

A. I think they are less objectionable because they are less in amount.

Q. Now how about the quality as well as the quantity? We have been speaking now of the quantity. How about the quality of the matter that escapes through these works and also the drainage canal?

A. As to quality, the effluent is not as objectionable as sewage when thrown into the river.

Q. I wil ask you professor, if it is not a known fact that the output from the sewage purification plants about which we have been speaking, is far superior to the water flowing out of the Chicago drainage canal?

A. I should judge that was so. You are asking me now again sanitary questions.

Q. Now professor, I understood you to say that you con-
7598 sidered the drainage canal as it is at present, an open sewer?

A. Yes sir.

Q. Now I will ask you if you have made any guinea pig experiments with that water?

A. Yes sir.

Q. Where were those samples of water taken with which the Guinea pig experiments were made?

A. They were taken at Lockport and I have here also samples from Bridgeport. Those from Bridgeport proved invariably fatal—those from Lockport proved sometimes fatal but not always.

Q. That was the Illinois and Michigan canal, wasn't it?

A. No, this is from Lockport, the drainage canal. The animals that died, died mainly of proteus infections.

Q. Now then professor, state what light those experiments poured upon the condition of the water in the drainage canal, or threw upon the condition of the water in the drainage canal, if any?

A. The specimen from the upper part of the drainage canal produced a condition of sepsis, and the animals promptly died from saprophytic poisons. Inoculations of specimens of
7599 the drainage canal at Lockport, did not always cause
death. The animals which died had proteus vulgaris infections.

JUDGE SPRINGER: Explain what that is.

A. The proteus injected into the peritoneum of the animal set up a peritonitis usually of a purulent type. The animal had an enlarged spleen, and bacilli in the heart blood. One animal died of sepsis, the same as at Bridgeport. There were evidently bacteria present pathogenic to animals in Lockport, not only toxic substances produced by saprophytes.

Q. Then they are not killed out by the water flowing through the canal?

A. No, not according to that.

Q. And they do enter the Desplaines river?

A. Yes sir.

Q. Then that is not altogether in line with what you previously stated, that they did die out in the canal?

A. My report showed the presence of this germ, but the proteus usually is not considered as a pathogenic organism to men under common conditions, when swallowed.

Q. Now what other explanation can you give for the typhoid dying out?

A. Only my experiments as to their behavior in sewage
7600 contaminated water.

Q. Your experiments were not parallel with the drainage canal were they?

A. I made no typhoid bacillus experiments on drainage canal water. Only on Lake Michigan water, and the others that I mentioned, the Illinois, Mississippi and Missouri.

Q. So then when you say that the typhoid germ has disappeared from the sewage of Chicago before it gets out of the drainage canal, you did not say so upon any experiments which you made with the life of the typhoid germ in the water of the canal?

A. No, that is only by analogy of the laboratory experiment, and the conditions existing in the drainage canal.

Q. Now professor, you stated Saturday that your examinations of the samples from the Illinois river, were made with such thoroughness, that if a single germ of typhoid had existed in any one of the samples examined, that you would have detected it, did you not?

A. No, I did not. If there had been a single typhoid germ in the water I would have detected it?

Q. Yes.

A. No sir.

Q. Well you mean by that you didn't make any such 7601 statement?

A. I did not make the statement that if there had been one typhoid bacillus in all the water received from there that I would have found it. I simply made the statement that I didn't find typhoid bacilli in that water.

Q. Now the typhoid bacilli might have been in the water that you examined, in the samples that you examined, and yet you not find them?

A. The possibility of finding the typhoid bacillus in water, when the water contains, we will say, one typhoid bacillus to a billion gallons of water ,is of course very remote.

Q. Well, professor, in these typhoid infected wells, there is more than one typhoid fever germ to every billion gallons of water isn't there?

A. Yes, at times perhaps, for short periods.

Q. And yet no bacteria of that character have ever been found. Might not professor, the typhoid bacillus be contained in the samples of water that you collected for your analyses and yet you not find it? That's what I want to know?

A. The possibility of a typhoid bacillus being in the river at Grafton, coming from Chicago is, in my view, of the matter, improbable.

Q. I am assuming now, professor, that in the sample of 7602 water that you examined, typhoid germs existed. Was your examination so accurate as to enable you to have detected it if it was there?

A. No bacteriologist is able to do that.

Q. That is just exactly what I want to know. You may find it and you may not.

A. Where it is very much diluted, it is possible that the typhoid bacillus may be in the water and the bacteriologist is unable to find it, if the dilution is very great. That is just the reason why I believe in indirect infection by typhoid bacilli, where polluting material enters the water.

Q. Now did you examine all the water contained in those little sample bottles sent you?

A. No sir.

Q. Which part did you examine?

A. I plated it out in the usual way, that is one cubic centimeter of the water being plated out of every specimen, and looked for all disease producing bacteria. When we did plate that out we would make no great or special attempt to discover the typhoid bacilli. With the past experience of polluted rivers, or even of polluted wells, where we know that near-by cess pools contain a large amount of sewage and typhoid discharges, we are unable to find them there.

7603 We do, in a general way, look for all typhoid-like organisms, in fact we have in our list a number of organisms that look similar, but when we come to run them through various culture media, we always found that they are not typhoid bacilli.

Q. So that you use only one cubic centimeter of water from each sample?

A. That is the amount that was used for plating most of the plates.

Q. Now how many samples of water did you examine with a view of detecting the typhoid fever germ if any existed.

A. We made about sixteen plates from most of the samples. Of some we made only ten plates.

Q. How many samples of water taken at the various times did you examine, with the view of detecting the presence of typhoid germs, of the Illinois river at Grafton?

A. Thirty-eight.

Q. Now then I understand you to say that in all you examined, 38 centimeters of water to detect the presence of typhoid germs?

A. No, we made about ten plates, ten to sixteen plates from each sample.

Q. And how much water did you use in each plate?

A. That varied. We used one-half cubic centimeter in some one cubic centimeter mostly, five cubic centimeters, sometimes in less polluted waters. We varied the quantity a little so as to obtain discreet colonies, separate colonies.

7604 Q. Now professor, I will get you to state, in the 38 samples of water that were examined by you for the purpose of detecting typhoid fever germs, how much would be the entire volume of water examined in round numbers?

A. Only a few cubic centimeters of each specimen.

Q. Now how much in the whole thing, according to your best judgment?

A. In all the 38 specimens?

Q. Yes, how much was examined for the purpose of detecting the typhoid fever germs? In other words, professor, a glass of water holding 200 cubic centimeters?

A. We have used of the Illinois river water about 120 to 130 cubic centimeters in all, about four ounces.

Q. Now that would be a very small glass of beer, wouldn't it?

A. Yes, rather small.

Q. Now assuming professor, that you used one small glass of water or in other words, about 130 cubic centimeters, how does that quantity of water compare with the volume of water flowing down the Illinois river?

A. I realize perfectly the difficulty of finding typhoid bacilli in infected waters, and I think I mentioned before, that for the reason of this great dilution it is difficult to find the typhoid bacilli in polluted waters, where we know the discharges of typhoid fever cases have entered. 7605

Q. Now professor, I will ask you if it would need great dilution in order to miss it in making only a few examinations like you did, whether it required great dilution to miss them?

A. No, not by this method. But we also used the enriching method.

Q. Considering that the amount examined by you is nothing more than a trifling infinitesmal part of the whole volume of water flowing through the river?

A. It is possible to miss the typhoid bacilli on account of dilution.

Q. Supposing that you had found the presence of one typhoid fever bacillus in each cubic centimeter of water that you had examined, what would you say as to the condition of the Illinois river with reference to typhoid fever germs.

A. If that were possible, people should be prohibited from using that water either with or without filtering.

Q. Professor, if you had found one typhoid fever germ in each cubic centimeter you had examined, wouldn't it be a fact that it disclosed a greater polluted stream than you have ever come in contact with in your bacteriological examinations?

A. Yes

7606 Q. Is it not a fact that if you had found one bacterium in each cubic centimeter you examined at the mouth of the Illinois river, that the condition of that water there would have been, from a bacteriological examination, far more impure and far less wholesome than the water in the Illinois river at Henry or at other places examined?

A. Yes, if I found typhoid bacilli in the water I would consider that very serious.

Q. Then professor, this inability or failure to find them, does it throw much light or any light upon an investigation of this character or upon their presence or absence?

A. Of the typhoid bacilli alone?

Q. Yes.

A. As to a general pollution, no; the absence of the typhoid bacilli would not say that a certain water is free from them.

Q. Free from them or not?

A. That can never be said when the findings are negative. It is possible, even if not probable. The things we find in bacteriologic examinations have more diagnostic importance than the things that we do not find.

Q. Now professor, you have made no examinations for typhoid germs in the Illinois river in mid-winter have you, especially from December 12th to February 24th?

7607 A. My examinations were made from February to October, 1900, and from October 3rd, to March 11th, 1901 and 1902.

Q. What were the results in winter time as compared with the summer time?

A. Well, I would have to have the tables to tell that. I cannot compare the results for the reason that the investigations in 1901 and 1902 were made at different places than those in 1900. I can however, compare Grafton. As to the findings summed up at Grafton, I find the colon bacillus and the proteus types, and there is no appreciable difference in the kind of pathogenic bacteria found during the two periods.

Q. ·Professor, in these examinations you did not take the quantity of any particular bacteria did you?

A. No, I never made any counts.

Q. And therefore no comparison can be drawn from these tables that can be relied upon?

A. Not as to numbers, only as to kinds, and the kinds were the same, there is no difference.

Q. But all things being equal, the science of bacteriology leads you to believe that there cannot be more of each kind in the winter time than in the summer time?

7608 A. There will be more of these kinds in spring and summer, when more pollution results, due to rains and other pollution. When the precipitation is less, there will of course be less pollution, and therefore in winter there is no doubt less general pollution than in summer or spring.

Q. In other words there was less saprophytic life in the winter time than in the summer?

A. Yes, that is not only due to the temperature, but also due to the fact that there is less pollution.

Q. As a matter of fact the same quantity of organic matter in the same volume of water, with that there is less saprophytic life is there not, in the winter time than in the summer time, is there not?

A. They multiply less in the winter time than in the summer.

Q. And because they multiply less, there is less saprophytic life in the winter time than in the summer time?

A. There is less saprophytic life. The other cause is the greater pollution that occurs during rainfalls that occur during the summer and spring.

Q. And when you say less saprophytic life, you mean less saprophytic activity?

A. Yes.

7609 Q. Professor, I will ask you if it is not a fact that the term "purification zone," or the zone of bacterial purification, is not a term that is used peculiarly by yourself?

A. It is not used peculiarly by myself, no sir.

Q. Used by all bacteriologists is it?

A. It is used by bacteriologists and it is used in hygiene. The zone of bacterial purification is a term which you find in every modern text book on hygiene.

Q. Can you cite a few cases in which it is referred to, in rivers for instance, where the bacterial purification is cited as such?

A. Yes sir. The Seine in Paris had, during the time of the experiments 70 kilometers below Paris, the same bacteriological flora that it had before it enters the city of Paris. The river Isar in Munich at 32 kilometers below the city of Munich has the same bacteriological flora that it had before arriving in the city of Munich. The purification zone of the river Oder, in Breslau, is 33 miles below the city. The purification zone of the Spree in Berlin—here conditions varied a little bit, because it flows into the Havel lake, a small lake, and as the river again leaves this lake, the purification is complete, a distance of nine miles from the city of Berlin. At Zurich, Switzerland, the Limmatt receives a very pure water from the lake, containing
7610 about 100 to 200 germs per cubic centimeter. This river purifies itself and is of the same bacteriologic flora as when it leaves the lake fourteen kilometers below the city of Zurich, which would be about nine miles.

Q. Professor, do you know whether or not the sewage of Berlin enters the river Spree?

A. Now it does not.

Q. Did it at the time those experiments were made?

A. It did at the time these experiments were made as much as I know.

Q. When were these experiments made?

A. These experiments were made in 1889 and 1890.

Q. Was bacteriology, the science of bacteriology at that time capable of determining that question?

A. I think the tables speak for themselves in that respect. I will just illustrate that by one example. Switzerland. After the river Limmatt containing 100 to 200 germs per cubic centimeter, passes through the city of Zurich, at Stadtmuehle it contains 160 to 6,000 germs; at the bridge of the Witkinger it contains 788,700 germs per cubic centimeter; at the Hoengger, three kilometers down, it only contains 150 to 16,000 per cubic centimeter. Eight kilometers down at the Kloster Fahli, it contains 900 to 17,000 and fourteen kilometers down, at
7611 Dietikon, it contains 250 germs again per cubic millimeter.

Therefore this distance of 14 kilometers has been called the zone of bacterial purification.

Q. Do you know when that was?

A. That was in 1890. Schlatter was the investigator.

Q. Do you know the conditions of the river at the time with reference to whether it was winter time or summer time or flood water?

A. The river comes out of the lake, Lake Zurich and simply flows through the city and receives there different sewage.

Q. Was it in winter time or summer time these experiments were made?

A. These experiments were made over long periods and more thoroughly than any others, except those in Munich. I have some figures here from Munich. These examinations were made all the year around.

Q. And it was fixed at one definite place?

A. And the place was practically always the same. These places I have mentioned in regard to the numbers of bacteria only, not as to the kind of bacteria.

Q. Now then in fixing the zone of bacterial purification, you as a bacteriologist, and whoever made the experiments along that line, have simply made them for the purpose of de-
7612 termining the presence of bacteria, without reference to the character and kind of the bacteria that exist?

A. They have been determined mainly to find out what effect sewage had upon the water, and whether it was possible for a river to free itself again of any bacterial pollution which it received.

Q. But professor, these determinations do not entirely enable one to determine that the river has been freed from sewage pollution, do they?

A. That the river has been freed of bacterial pollution only; not of chemical or other conditions.

Q. Does the science of bacteriology enable you to determine the place in a running stream where it has been freed from disease producing bacteria caused by the discharge of sewage into that stream?

A. Under the conditions which I have stated here, yes.

Q. Then professor, if it is possible, bacteriologically to obtain reliable information as to the disappearance of disease producing germs deposited into a river, with the sewage from the city, why are you not able, and why is not any other bacteriologist able to state as a bacteriologist without the aid of chemistry, without the aid of the extent of the pollution, the source of the pollution, without the aid of the volume or stream flow, the
rate of stream flow, the exact place where purification is
7613 taking place from the pathogenic germs, purification from
pollution from pathogenic germs?

A. We do. The bacteriologist claims that with the disappearance of the saprophytes the pathogenic bacteria have disappeared. Why? Because the pathogenic bacteria will disappear very much sooner in water than saprophytes.

Q. Then professor, you take the position that as a bacteriologist pure and simple you can determine the sanitary condition of the water in a running stream?

A. Only in regard to that particular question stated,—the question of what becomes of the pathogenic germs in the sewage and in the river, when the sewage gets into the river. According to the experiments made on the subject, I see no other way out of it excepting to conclude with these data that bacterial purification takes place. Our laboratory experiment tells us that pathogenic bacteria die long before non-pathogenic do, and that the more the saprophytes multiply the sooner the path-

ogenic bacteria are destroyed, and therefore, if I see the numbers of bacteria in a river rise to millions after sewage enters it, and then after a certain distance of flow decrease to the normal number of a non-polluted stream, I must conclude that the saprophytes have died and disappeared, and the parisites too, and long before, because the conditions for them are more
7614 unfavorable than for the saprophytes, that is the reason.

Q. Professor, assuming that in Lake Michigan bacterial analyses should show no pollution of any considerable consequence, in other words show less pollution than the Illinois river does at Grafton and it should be proven to you that the water in Lake Michigan as drawn through the water mains into the water supply of the city of Chicago had produced typhoid fever, what would you say then were your conclusions as to the absence of pathogenic and disease producing germs at the intake cribs, was it a conclusion or opinion that could be relied upon?

MR. DRENNAN: I object to the question for the reason that the witness is not called upon as an expert to give an opinion as to the value of his own testimony?

A. Not as to its sanitary condition, but as to the disappearance of parasites before saprophytes.

Q. Professor, you conclude simply that because the saprophytes have disappeared, that all parasites are gone?

A. If you conclude—

Q. Answer the question?

A. I will.

Q. Do you, from these analyses conclude that inasmuch as the saprophytes have disappeared, that all parasites have
7615 gone before?

A. Long before.

Q. Then professor, the absence of saprophytes in the water of Lake Michigan necessarily means that the parasites have gone before, although that water when taken into the human system by the people of Chicago produces typhoid fever?

MR. DRENNAN: I object to that assumption on the ground that there is no evidence that the water of Lake Michigan has ever caused a person drinking it to become infected with typhoid fever, or is free from saprophytes.

A. If Lake Michigan water had been badly polluted with much sewage and the bacteria had increased up to millions, and the tap water should contain millions of bacteria, we may take it for granted now that some of the water containing typhoid bacilli had also been taken in at the same time. If the saprophytic bacteria in that water disappeared, it is quite certain that before they disappeared, that the pathogenic bacteria must have disappeared, but if we put the typhoid bacilli into pure lake Michigan water, where there is little or no organic material and where there are no other saprophytic bacteria, then the typhoid bacillus may live in that water for some time, but it will be tremendously diluted of course, under those conditions.

7616 Q. But it is there nevertheless?

A. It is there nevertheless, therefore I have always tried to make that clear. I draw these conclusions only by the great increase of saprophytes, showing that there really is something there which is destroying pathogenic bacteria and that if pure water is inoculated with typhoid bacilli, there is nothing to destroy them. They simply have to die out from starvation, lack of organic material, etc. It is quite a different thing if you have sewage pollution and pathogenic bacteria with it than when you have pure water and pathogenic bacteria. In the first case pathogenic bacteria die sooner than if you put pathogenic bacteria into pure water free of organic material and saprophytes. If at a previous examination we found millions of saprophytic organisms, as we have them here in the drainage canal and then saw the saprophytes disappear, it is quite certain that the parasites must have died long before the number of the saprophytes decreases markedly.

ADJOURNED until 10:00 A. M., Tuesday, October 6, 1903.

10:00 A. M., Tuesday, October 6, 1903.

7617 Continuation pursuant to adjournment

Present, the Commissioner and same counsel representing the respective parties.

PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination by Mr. Jeffries and testified as follows:

Q. Professor, is this bacterial purification zone to which you have referred in your direct and also in your cross-examination sharply defined?

A. Yes sir, that is very sharply defined.

Q. Can that point always be determined?

A. Bacterial purification is usually determined by the number of bacteria rather than by the quality of the bacteria. In all the experiments which I have made, or in these cases which I have mentioned.

Q. You define the zone of purification simply by the great reduction of bacteria of all characters?

A. The bacteria of all characters, yes sir.

Q. Without reference to whether those bacteria be pathogenic or non-pathogenic?

A. Yes, in all instances which I have given, that was so.

7618 Q. I will ask you professor, if that zone is not continually changing from day to day?

A. Yes sir, that zone is continually changing. I would like to give here an illustration of continously increased pollution and continuous purification. You spoke of the river Dee. This river Dee above Braemar shows 84 colonies per cubic centimeter, below the old Mar Castle; after receiving the sewage of Braemar, 2,829 colonies per cubic centimeter were found. Below at the bridge of Ballater, 1139 colonies were found. Below Ballater, after the sewage effluent of Ballater has entered the river, 3780 colonies per cubic centimeter were found, whereas the effluent of Ballater contained from 235,000 to 26,000,000 per cubic centimeter. At Kincardine, O'Neil, 938 colonies only were found in one cubic centimeter. After the junction of the river, Neil-burne, again 860 colonies were found in one cubic centimeter. The Neil-burne, 12 yards before the sewage outfall of the river contained 1,200,000 colonies per cubic centimeter. In Invercarnine, only 950 colonies per cubic centimeter were found, so we have here a reduction in the total of 40,000,000 a rapid pollution and a rapid bacterial purification, and in spite of all these pollutions of sewage containing 26,000,000 germs per cubic centimeter and in the other case 1,200,000 per cubic centimeter, you have finally again only 950, per cubic centimeter.

7619 Q. Where do the bacteria disappear in these instances?

A. At Invercarnine.

Q. What became of it?

A. The organic material which entered the river, with rapid multiplication of the saprophytes, accounts for the increase of bacteria, and as the organic material became less, was consumed, was eaten up by the bacteria. The conditions for life and multiplication of saprophytic bacteria became unfavorable and they died out.

Q. Do you know this for a fact or is this your theory?

A. This is a fact which holds true in all cases, of rivers, that the rapid multiplication of saprophytes corresponds to the great quantity of organic matter present, and that if these great numbers of saprophytes disappear, the organic matter has been consumed.

Q. That is your theory of the matter?

A. That is not a theory. That is something which we can see in the laboratory right along. When the organic material in a water has been consumed by the immense multiplication of the bacteria, the number of bacteria decreases from day to day.

Q. Professor, I will ask you if anyone ever examined the mud in the river Dee, or do you know?

A. Not that I know of.

7620 Q. Then you do not know but what large quantities of the bacteria do disappear in the mud and sediment?

A. The sedimentation—

Q. I want to know if you know now?

A. I don't know.

Q. With reference to this particular stream.

A. I don't know.

Q. Now I will ask you professor, whether or not it was determined from the analyses of the water in the river Dee, that the bacteria remaining were pathogenic or non-pathogenic, disease producing or non-disease producing?

A. In that particular instance, that was not the question to be determined. The question to be determined in this instance was simply how does the sewage entering the river, increase the total number of bacteria and do they disappear again.

Q. And no distinction was made between the sewage proper and the effluent of the sewage?

A. No, no distinction was made.

Q. Then your position is that because of the rapid disappearance of the bacteria in the effluent, the same condition would be true with reference to the sewage proper and that the water in the river after it reached that particular point 7621 was freed from the disease producing germs, whether it be the reduction of the effluent from the bacteria, or the reduction of the sewage proper from the bacteria?

A. I do not know with regard to that in that particular case.

Q. And what is true with reference to that particular case will apply to any river with reference to the zone of purification will it not, from your own standpoint?

A. That the more organic material there is present in the river, the more the water bacteria and saprophytes will increase.

Q. With reference to the nature and character of the remaining bacteria in the water, whether it comes from the untreated sewage of the city, or whether it comes from the effluent of the sewage of the city?

A. I am speaking now only of numbers of bacteria in this case, and I say the greater the number of saprophytes, the greater must be the quantity of the organic material that has been poured into that river, else those saprophytes would not be there, and the disappearance of the saprophytes in the purification zone means also the decrease of the organic material.

Q. But professor, does the disappearance of the organic material necessarily mean the death of the pathogenic germs or disease producing germs?

A. Yes, because the saprophytic bacteria die later than the pathogenic bacteria—

7622 Q. That depends, doesn't it upon the temperature of the water?

A. That depends not only on the temperature, but it depends mostly on the overgrowth of the saprophytic bacteria which destroy the pathogenic bacteria. The pathogenic bacteria cannot exist when they are in small numbers present in millions and millions of saprophytes.

Q. Professor, do you know of any cases in Great Britain or in the United States ,in which the instance of the bacterial zone of purification has been so well established, that the water below it is considered by competent authorities, safe for drinking purposes?

A. The epidemiologist who neglects entirely the bacterial questions and their significance, of course condemns all waters which are polluted, but the bacteriologist speaks of a zone of bacterial purification due to those conditions which I have mentioned many times.

7623 Q. Professor, assuming that the sewage of the city of Cumberland is discharged into the Potomac river, and that the city of Washington is situated on that river 160 miles below Cumberland, and assuming that from a bacteriological standpoint the zone of purification had taken place in that river ordinarily 40 miles below Cumberland, and assuming further that there was a typhoid fever epidemic in the city of Washington, and assuming that that typhoid epidemic was the result of a previous typhoid epidemic at the city of Cumberland which discharged its sewage into the Potomac river—

A. That is a theory.

Q. Just wait. This is an assumption. There is no theory about it.

I would like to ask you what effect and what bearing the ascertainment of the zone of bacterial purification at a point ordinarily forty miles below the city of Cumberland would have upon establishing the sanitary condition of the water of that river, after it had received the sewage of Cumberland and passed down as far as the city of Washington?

A. If it was proven bacteriologically that at forty miles the bacterial purification and the disappearance of saprophytes, and the consequent decrease of the organic mattter which it must have contained, according to your assumption, had taken
7624 place, then I would judge that with the disappearance of the saprophytes at forty miles in the zone of bacterial purification, not only the saprophytes would have died by that time, but that all the other pathogenic bacteria would have died before that time, and that therefore an epidemic of typhoid fever 160 miles away from the source of such pollution, according to bacteriologic judgment, would have been due to other causes. and that the water, if condemned, was condemned on suspicion

only, because there has been a typhoid epidemic higher up on the river.

Q. Now professor, on the basis of the previous question, we will assume that it is an established fact that a typhoid epidemic at the city of Washington, was caused by a preceding typhoid epidemic in the city of Cumberland, on the Potomac river 160 miles above Washington. Now with the assumption that the typhoid epidemic at Washington was caused from the people of that city drinking the water which had been infected with the typhoid germs of the disease at Cumberland, of what value then, is the ascertainment of the zone of purification when that, according to the bacteriologist, would be ordinarily about 40 miles below the city of Cumberland?

A. Yes, but such an assumption is impossible, according to my view.

7625 Q. Well, we are assuming that to be a fact, now, aside from your views?

A. Yes, but the assumption is an impossibility. I think that in a case like that it is much more probable that the typhoid bacilli have been brought by a patient, directly and not by way of the water, to the city of Washington, 160 miles below.

Q. But assuming, professor, aside from your theory, or from the investigations that you have made, that the typhoid epidemic occurred in Washington and that it was the direct result of people drinking the water from the Potomac river, which had been polluted with this typhoid infected sewage at Cumberland, 160 miles from Washington. Of what value would the ascertainment of the bacterial zone of purification, which is ordinarily 40 miles below Cumberland, be in determining the sanitary condition of the water at Washington?

JUDGE SPRINGER: I object to this question for the reason that there is no evidence in this record that the zone of bacterial purification in the Potomac river is fixed at 40 miles below Cumberland, and further I object to this question for the reason that it ignores entirely the most important factor in reference to the Potomac river, namely it is a rapid flowing stream, it being a mountain stream, from its source to

7626 the city of Washington.

Q. (Question repeated).

A. If we were able to find at Washington, in the river, typhoid bacilli, and you were unable to find them forty miles below Cumberland, in the zone of bacterial purification of saprophytes, then of course you would have to conclude that the infection must have been nearer Washington rather than from Cumberland. It would have to be proven that typhoid bacilli must be found not only at Washington, but also higher up on the river. I consider that the only proof.

Q. Professor, I have cut out all of those conditions in the question, which of course cannot be of any harm to you.

A. Yes, but it is an impossible assumption according to my theory.

Q. Here is the proposition now. We are assuming that there is an epidemic at Washington—

A. Yes.

Q. We are assuming that prior thereto there was an epidemic at Cumberland?

A. Yes.

Q. We are assuming that the typhoid dejecta of the patient at Cumberland passed into the Potomac river through the sewers of that city. We are assuming further that the typhoid infected
water flowed from Cumberland down to Washington and
7627 produced the typhoid epidemic at that place. We are as-
suming further that the zone of bacterial purification has ordinarily been found at a point about forty miles below Cumberland. Now then I want to know what effect those assumptions being true, the ascertainment and the determination of the bacterial zone of purification being ordinarily 40 miles below Cumberland, would have upon the sanitary condition of the water at Washington?

JUDGE SPRINGER: I object to this question for the rea- that these assumptions are impossible, and purely theoretical; that any answer the witness can give to this question will be irrelevant to the issues in this case, for no such assumptions can exist, and that therefore any answer or testimony in reference to such assumptions will be of no value in the case and it will not tend to establish any of the issues involved.

MR. JEFFRIES: I suggest that the question is not so much a theory as a direct and correct ascertainment of the zone of purification.

JUDGE SPRINGER: My objection is that none of these things has been ascertained as to this river; no bacterial examinations have ever been brought to the attention of the Commissioner, or brought into this record, and that according to the knowledge of the witness, and according to my understanding, most of these assumptions are utterly impossible and
7628 irrelevant therefore to the issues involved in this case.

A. Well, it is a pure hypothesis, and I can only answer it as such, that in that case, if that all was proven, we would prohibit the use of the water.

Q. And the ascertainment of the zone of bacterial purification would be valuless?

A. Would be valuless.

Q. Now professor, I will ask you if it is not a fact that this zone of bacterial purification moves up and down the river according to the amount of pollution, the amount of dilution, the temperature of the water, the volume of flow, the rate of flow, and with reference to flood seasons, and dry weather seasons?

A. Yes sir.

Q. Then it cannot be fixed at any one particular time so as to be found at that particular point at all seasons and at all times of the year?

A. The particular point is only established on an average of many examinations.

Q. Now then professor, going back to the hypothesis which we gave you in reference to the typhoid epidemic at the city of Washington, I will ask you if it is not entirely possible and reasonable from your standpoint alone, to believe that
7629 if the typhoid fever at Washington is assumed to have
been caused by the infected water or the infected sewage of Cumberland, 160 miles away, and that the typhoid epidemic at Washington was the direct result of the deposit of the infected sewage at Cumberland into the Potomac river, that the zone of purification had not established itself until after the water had passed Washington, while at other times it might have

established itself further up the river, between Washington and Cumberland.

A. I do not believe that the zone of bacterial purification will vary within such large distances as 40 and 160 miles, because the disappearance of saprophytes takes place with the disappearance of organic material, and taking the average for the exminations of a whole year, the variations will not be 120 miles.

Q. Is it a question of distance or a question of time?

A. It is a question of sewage being present in greater or smaller quantities, and the question of temperature and the question of dilution.

Q. It is not then a question of distance?

A. It is a question of distance in one respect also, with regard to the rapidity of flow of the river, this bacterial zone of purification may be moving up and down somewhat
7630 with the variations of those conditions, but the variation would not be within such wide limits as 120 miles.

Q. Isn't time required to effect the saprophytic elimination?

A. Yes but the time depends entirely again on temperature; that is, at a favorable temperature the time will be very much shorter than at an unfavorable temperature.

Q. And if the time and the temperature were unfavorable, the time would be very much longer, and of course the distance traveled would be very much further would it not, the flow being the same at all times?

A. There are so many factors—

Q. If the temperature is unfavorable, for the saprophytic bacteria, it is unfavorable for the pathogenic bacteria is it not?

A. No, that is not the conclusion. The favorable temperature for pathogenic bacteria is the temperature of human blood, so if the temperature is lower than room temperature, at which saprophytic bacteria grow less rapidly, then the saprophytes will grow slower, so there would be a question of lower temperature. If the temperature is lower the saprophytes do not increase—

Q. Do you mean, professor, that the pathogenic germs 7631 will live longer in warm water than in cold water?

A. Not necessarily. It will multiply in higher temperature, and will not multiply at a low temperature.

Q. We are cutting out now the proposition of the pathogenic germs multiplying, and we are leaving them in the condition that they came from the human system, from the excreta. I will ask you if it is not a fact that the lower the temperature of the water the more unfavorable for saprophytic elimination, and the more suitable for the life of the pathogenic germ, is that not true?

A. That also will vary considerably. We have no exact data. They are only observations.

Q. Then professor, if those things are variable according to the temperature of the water, according to the amount of organic matter deposited, according to the saprophytic growth, or saprophytic elimination, I will ask you why it is that there is not a great variation in the place where the bacterial zone of purification is established in any river?

A. Well, I think I can explain my position easily. A disease producing germ when kept at a high temperature will multiply and when it multiplies rapidly it will produce toxins and poisons which are poisonous to itself, and therefore will die sooner, which would not be the case if that same room be kept at 7632 a low temperature.

Q. Now professor, you are speaking altogether of the laboratory experiment, are you not?

A. Well, that is a biological factor—

Q. I want to know then if that be true, if you have ever known of the pathogenic germ multiplying in a running stream?

A. No.

Q. Have you ever known of its multiplying in an open sewer?

A. No.

Q. Do you have any reason to believe that they will multiply?

A. In an open sewer?

Q. Yes?

A. No.

Q. Then, professor, we must eliminate the question of multiplication in the determination of the presence of pathogenic germs in running streams and in sewage, must we not?

A. Yes.

Q. Then I want to ask you if it is not a fact, taking the water in the stream or the sewage in the Chicago drainage canal that the lower the temperature of water the less probability there is of the disease infecting germs dying out?

A. They will die out more rapidly in cold water than they will in warm water.

7633 A. They will die more rapidly in cold water, than in warm water when saprophytes are present with them and organic material.

Q. The disease producing germs?

A. The disease producing germs.

Q. Well, now, what is it in cold water that brings about their death?

A. The unfavorable temperature first, prevents of course, multiplication, and at low temperatures, while they may exist for a long time, they are certainly influenced unfavorably.

Q. Professor, you say it prevents their multiplication. Now that you have eliminated the question of multiplication, because you said you had never known any of them to multiply in the river or in the sewage—we are dealing now with the question of longevity, of vitality, of ruggedness and the ability to live. We put pathogenic germs into cold water; we put pathogenic germs of the same character in hot water, which will live the longer?

A. Well, that will vary as a general proposition. It is generally said that they will live longer in cold water than in warm water, but that depends upon other bacteria present in the water. I can say nothing definite with regard to that question. In cold water it would depend on other bacteria present how long they would live. In warm water they might
7634 even multiply. Many of them will live longer in cold water than in warm water if the water is sterile.

Q. Then professor, it is absolutely impossible from your laboratory experiments, to determine anything with reference to the life and character of disease bearing germs in a running, stream is it not?

A. That depends also upon the presence of other bacteria.

Q. I will ask you professor, if it is not a fact that what you learn of the life characteristics of disease producing germs, in the laboratory, is very unreliable, and very limited, so far as the life in the running water is concerned?

A. The laboratory conditions are certainly somewhat different for the pathogenic germ in the test tube, than they would be in the open river, or in the open sewer, but if these conditions are made as similar as possible, then there is only one feature remaining, and that is the products or excretions of other bacteria in the mixture with the typhoid bacillus, that constitute a difference. The other conditions can be made, practically made alike to those in the river.

Q. Now professor, coming back to this zone of purification. Do I understand you to say that it may always be found within certain limits, or do I understand you to say that it may be very remote from the point of pollution, and that it
7635 may be removed long distances upon certain physical
conditions which manifest themselves in the water of the river?

A. The zone of purification in a river may move up and down, according to the elements of rapidity of flow, the temperature and the amount of water.

Q. Hasn't the amount of sewage got anything to do with it?

A. Well, it is that which gives rise to the increase of bacteria. With regard to the zone of purification I am speaking of bacteria, that is the zone of bacterial purification.

Q. How remote is this zone of purification from the source of pollution?

A. That will vary according to those conditions mentioned.

Q. May they be as remote as 100 miles?

A. Usually not as much as that.

Q. May it not be much more than 100 miles?

A. No, it should be much less than 100 miles.

Q. Are you not aware, professor, that competent bacteriologists have placed it as far off as at least 160 miles?

A. I am not.

Q. May it not be even more remote than 160 miles?

A. Not in my opinion.

7636 Q. Professor, you stated, I believe that the conclusion of the British River Pollution Commission was that there is no river in Great Britain long enough to purify itself from sewage introduced into it even at its source?

A. I did.

Q. And that that conclulsion is no longer necessarily accepted?

A. That that conclusion is not accepted by bacteriologists.

Q. Now then, have English authorities on sanitation ever withdrawn or corrected that statement?

A. According to the experiments I mentioned today, of the bacteriologist Frankland, with regard to the river Dee, in July, 1892, that ought to be withdrawn.

Q. But you don't say that it has been withdrawn?

A. It has been denied absolutely in Germany.

Q. Have the English authorities denied it and withdrawn it?

A. Some English authorities still continue that prejudice, in spite of the work of the bacteriologists.

Q. Professor, I will ask you if there is any other people on the face of the earth that have made more thorough investigations of this subject than the English people?

A. Yes sir.

Q. Who are they?

A. The Germans.

7637 Q. Are there any better authorities upon the pollution and purification of rivers in general than the English?

A. They must have had very, very bad conditions there, and it was not until bacteriologic research thoroughly investigated those conditions, that this statement with regard to "no river being long enough to purify itself of any pollultion it receives in its course" was disproven--bacteriologically disproven. That statement dates back to the time when such subjects were treated without much bacteriological research or without much chemical research even, and that statement was given up by a good many as soon as bacteriological research proved its incorrectness.

Q. But professor, with all the bacteriological examinations of water, and with all the conclusions that they have drawn with reference to the bacterial zone of purification and the self-purification of streams, I want to ask you if it is not a fact that human experience with reference to the rivers investigated and considered, has not always been the same?

A. In spite of all the investigations by the bacteriologists into the subjects, people have retained their objections to turning sewage into rivers as a general proposition; if for no other purpose than that of preventing a nuisance in the river at the time and place where the sewage enters the river.

7638 Q. Isn't it a fact, professor, that in the face of all that bacteriology has determined with reference to the self-purification of a stream, the bacterial operation of the organic substance that is deposited into the river, that the experience of the human family with reference to those rivers, has always been the same, has remained the same since those discoveries were made by bacteriology, as it was prior thereto, and that the people now living upon those streams, polluted with the sewage of large cities, are using a more determined effort, and stronger effort, and greater effort, and more accurate means of freeing those rivers from pollution than it did prior to these bacteriological discoveries?

A. That was the very result of the bacteriologic investigation. No city should use water from a river, unless that river water be filtered, even if it did not receive the sewage of a city, it would be polluted by all sorts of material entering it, after rains and from various industrial establishments, so river water has always been by the public looked upon as dangerous to use, even if it did not receive any sewage. Industrial products from factories, and so on, may be much more harmful than the decomposed sewage of human beings.

Q. Professor, assume that a city has grown up on the 7639 banks of a stream and has used the water of that stream from the time of its foundation, during the entire history of the city, and that suddenly upon the banks of that stream above, a large and populous city of more than three times the population of the former city, should suddenly begin to discharge its sewage into that stream upon which the former city was located, what attitude would the former city occupy in the minds of the civilized world with reference to this water supply, speaking from a scientific standpoint?

A. Have you mentioned any distances in your question?

Q. I mentioned no distances of any kind.

A. What is the question?

Q. (Question repeated.)

JUDGE SPRINGER: I object to that question for the reason that it is based upon assumptions which do not exist, have not existed and cannot be proven to exist in this case, and that any answer predicated upon such assumptions would be irrelevant, incompetent and immaterial, for the purpose of establishing any of the issues involved in this suit.

A. I would say that it would have been wrong of the first city under all conditions, to use the water of that river, even if no city had grown up upon the banks of this river above.

7640 Q. What would you say as to the second city discharging its sewage into the river, and what effect would that have upon the intelligence of the civilized world?

A. That would be a question for the sanitarian, and the chemist and the bacteriologist to decide, as to what effect it would have upon the health of the people of the second city. The other is purely a matter of sentiment, and we all have objections to the turning in of sewage into a river, if we are located below on the river a short distance, and the shorter the distance below, of course the more serious would be such objection.

Q. Professor, if you were employed to remove the sources of pollution from a running stream all things being equal, would you commence at the mouth of the stream or would you first commence at its source and pass down the river, clearing the sources of pollution away?

A. It is impossible to remove all the sources of pollution of a river which receives the sewage or receives the products of various industries. Even the most modern filtration plants will not prevent all organic substances from passing through those filters, and if they are located a short distance above the city that is using that water, it is all a question of dif-

ference in dilution, with regard to inorganic substances, and
with regard to organic substances it is a question of thor-
7641 ough destruction of the organic material, a distance long
enough above the city using such water, that it can be
called safe in that respect, but even then filtration must be used, because continuous new pollutions will take place all along the river by all other sources. Even if all the cities along the Illinois river would stop turning their sewage and other products into the river, there would still be pollution of that river by rains, by ships, and other unavoidable pollutions by industrial agricultural products. Rains would wash all kinds of impurities of the surrounding country into the river. It cannot be avoided, and is, therefore, a constant source of pollution. If it wasn't for continual bacterial purification, you would not have as little disease in St. Louis as you have now. It is due to repeated and continual bacterial purification which takes place all along the river, after repeated and continuous pollution of the river. That is the best evidence of the great value of bacterial purification and the destruction of pathogenic bacteria.

Q. In other words, professor, a half a loaf is better than no bread at all, is that true?

A. Yes, certainly, that is true.

Q. Professor, I am going to ask you again as a biologist,
pathologist and a bacteriologist, that if authority was given
you to remove all the sewage source of pollution in a given
7642 stream, if it is not a fact that you would commence first
to remove the sources of pollution at the source of the
river rather than at its mouth?

JUDGE SPRINGER: I object to this question for the reason that there is no power on earth that can give such authority to a human being. It is an utter impossibility to keep sewage out of the river, as much as it is impossible to keep rain out, and that any answer that this witness should give to that question would be immaterial, irrelevant and of no value in establishing any issue in this case.

MR. JEFFRIES: I suggest to the counsel that the Thames Conservancy looks after the condition of the Thames river, and keeps the sewage discharges of the cities from entering that river.

JUDGE SPRINGER: I would suggest that they approximately do, but to say that they actually do, is contrary to the condition that exists there, and that are known to all those having charge of the London waterworks. They endeavor to protect the sources of the river above the water intake, and accomplish it in a great many respects, but not all respects, it is utterly impossible.

MR. JEFFRIES: They certainly improve the condition of the River Thames, or the Conservancy would not be maintained.

Q. (Last question repeated.)

7643 A. I would not take such a responsibility, because I know that that would be impossible, to remove the pollution from the river.

Q. We are speaking now of the sewage pollution and all possible sewage pollution that might be under modern contrivances, eliminated from the river?

A. It cannot. For instance, every heavy rain will sweep all the material from all the farms along the river, into that river.

Q. Then, professor, as a bacteriologist, as a biologist, and as a pathologist, should not every endeavor be made to permit as little sewage from towns and cities entering the river, as is possible and pratical under modern conditions?

A. Modern cities have to get rid of their sewage or effluents and they will have to dispose of it in some way, and what shall they do with it if not turning it into the river and depending upon the natural purification, bacteriological as well as chemical? That is the way to dispose of it.

Q. Are you familiar with Berlin?

A. Yes, I am.

Q. Do you know the system of sewage disposal there?

A. Now, only the effluent is turned into the river Spree. Formerly the sewage entered the Spree itself.

7644 Q. In other words, then, there is a great populous city that has, to a large extent, eliminated the sewage from the pollution of the stream?

A. Because much of the water was used a short distance below the city of Berlin and it was obnoxious to the senses, it was physically as bad as that of the river Seine in Paris. Black thick scum, even dead animals were floating around on the river, and big gas bubbles would come up. The people below Berlin had to use the water, and they had to be protected. It would be just the same here, as though you had people living along the drainage canal and they would have to use the canal water for drinking purposes. They would object to the odors of the big sewage tank in the upper part, particularly they would object to the odor. They would object to the use of that water, and some provision would have to be made for them. If we had to provide for those people, it would be the same condition as it existed below Berlin.

Q. But they have made those improvements?

A. For the reasons stated.

Q. I am not talking about the reasons now. I want to know whether they did or not?

A. Yes, they did; they made those improvements for 7645 the people living shortly below Berlin, but those living further down were not the ones affected or complaining.

Q. Now professor, this bacterial zone of purification depends largely upon the amount of sewage in the stream, does it not?

A. Yes sir, the more sewage the more rapid the disposal of the disease producing bacteria on account of the overgrowth of saprophytes.

Q. Then the more sewage means a change in the position of the zone of purification?

A. That alone, no. The more sewage and the more favorable the temperature for the growth of saprophytic bacteria in that sewage tank, the sooner the disposal of the organic material and the earlier will be the purification zone.

Q. The more sewage with an additional increased flow, means a change in the position of the bacterial zone of purification, does it not?

A. Yes sir.

Q. Now then, assuming that Chicago has a population of 4,000,000 of people rather than a population of 1,600,000, as now discharging the sewage into the drainage canal, the additional discharge produced by the increased number of popu-

lation with an additional flow would necessarily move the
7646 zone of bacterial purification down the Illinois river,
would it not?

A. That condition could be made so that there would not be much difference, so that there would not be much shifting of the zone of bacterial disappearance.

Q. Well, why?

A. Well, the more organic material with a certain head of water—

Q. No, but we are basing the assumption upon the idea that the water will be increased as the pollution is increased.

A. Yes.

Q. So that the stream will be very much quicker in flow?

A. This is mainly a question of dilution. The greater the dilution the farther down will be the zone of purification.

Q. Professor, if there is deposited into the drainage canal, the sewage from 1,600,000 people, when that drainage canal is taking from the waters of Lake Michigan 250,000 cubic feet of water per minute, would there be any change in the dilution if the sewage of 3,200,000 people should be discharged into that canal when the canal draws from the Lake 500,000 cubic feet of water per minute—what would be the difference in dilution?

A. It would be the same.

7647 Q. It would be the same, that is it exactly. Now then
if the dilution under those circumstances would be the same, would not the increased volume of water from the lake and the increased sewage polluted water coming through the canal, create a more rapid current, and therefore remove the zone of bacterial purification farther down the river?

A. Yes sir.

Q. Now professor, I will ask you if it is an easy matter to detect typhoid bacilli in sewage?

A. No sir.

Q. Isn't it a difficult matter, professor, to distinguish between typhoid bacilli and coli in sewage?

A. Yes sir.

Q. May not the disappearance of typhoid germs in your experiments be due largely to an overgrowth of coli, rather than the actual death of the typhoid?

A. You mean in the waters of the Illinois river?

Q. Experiments that you made?

A. Well, do you mean laboratory experiments or do you mean river water examinations?

Q. I am talking about the experiments now that you made.

(Previous question read.)

A. In the water experiments made with Lake Michigan water there were no colon bacilli; they were mainly cocci or large water bacilli.

7648 Q. Well, there is no coli bacilli in the waters of Lake Michigan?

A. Sometimes; not always.

Q. Then you made no experiments under that condition?

A. With Lake Michigan water—it contained no coli bacilli.

Q. With the river and the—

A. With the river water—our specimens of water were free from the colon types of bacteria in the Lake Michigan water. With regard to the rivers, we did have colon bacilli in our specimens.

Q. May not the disappearance of the germs—

A. I found them for days, and then I could not find them any more.

Q. Then the colon bacillus had so grown that you could not find them?

A. In all bacteriological tests the finding of the germ is evidence. If we do not find the germ it is not as good negative evidence as the other is positive.

Q. In other words, not having found them did not mean that they were not there?

A. Because we have usually a large quantity of water and we have not examined all of it.

Q. And you have a large production of the colon?

A. We have a large production of the coli types if present; they grow rapidly.

7649 Q. And which you cannot easily distinguish from the typhoid?

A. Oh yes, you can distinguish them, but there are some difficulties, considerable difficulties in distinguishing a typhoid bacillus from a coli bacillus.

Q. Then in your examination of the life of the typhoid germ in the Illinois river water, the disappearance of the typhoid germs from that water that you examined may be due largely to an overgrowth of the coli rather than the actual death of the typhoid, may it not—or may have been due?

A. I think I have been very careful in those experiments, and I have been able to find them for days, even in such very small quantities as I have inoculated into those waters. The difficulties were great on account of the colon types being very numerous. I judge from the results of these experiments, that if I am able to find them at all for five or six days, and thereafter am unable to isolate them, that they must have disappeared or died.

Q. But still, on account of the great numbers of colon bacilli which have been produced, they may be there and you not find them?

A. The great numbers of colon bacilli that have been produced may have been the cause of the death of the typhoid bacillus. 7650

Q. And still they may be there and you not find them?

A. I would rather say they must have died, due to the overgrowth of colon bacilli, but not that they are there.

Q. Do you know that they died, and do you know that they were not there simply because you didn't find them?

A. Yes, it is my opinion that they must have died because I found them before when the difficulties were just as great. We can have opinions in such things, and we may be mistaken.

Q. Well, it is merely an opinion then?

A. Well, my opinion is that they have died, due to the great increase of other bacteria in that water, colon bacilli types among the others.

Q. Now then, professor, the condition of that water—what was the temperature of that water at the time those examinations were made?

A. Ten to twelve, centigrade.

Q. And that would be how much Fahrenheit?

A. 50 to 53 Fahrenheit.

Q. Now then that is supposed to have represented the temperature of the water in the river?

A. That is supposed to have been as near the temperature of the water as it was then.

7651 Q. Now then, if those experiments had been made with the water at 32 Fahrenheit, there would not have been such a growth of the colon bacilli, would there.

A. All the bacteria—you speak now of Fahrenheit?

Q. Yes.

A. —At 32 Fahrenheit, would have frozen.

Q. There would have been no increase then, would there?

A. There would not have been any increase, no.

Q. At 33 Fahrenheit, there would not have been as much increase as there was at 53?

A. No.

Q. Then if there would not have been as much increase at 33 and the examinations had been made at 33, the typhoid bacilli would have better opportunities and a better chance to live, would they not?

A. I don't think there would have been any difference between 32 and 50 with regard to the growth of typhoid bacilli.

Q. Do you think temperature has nothing to do with it at all?

A. Oh so little, no; such a few degrees that is.

Q. Then why didn't you make all the experiments at one certain point and make no variations whatever?

A. I simply wanted to produce a low temperature, that was all—conforming somewhat to the temperature of the river water, that was the only object.

7652 Q. Don't you know that the temperature gets much lower than that at times, and much higher than that at times?

A. I don't know the temperature of the Illinois river, but I took it that the temperature of river water in general is 10 to 12 and so I took those temperatures, and it varied between those degrees in the refrigerator.

Q. You think then the change in the temperature of the water has very little to do with the life of pathogenic germs?

A. Slight variations, like that; but greater variations if you take blood temperature, now, 98 that increases the growth of the typhoid bacilli.

Q. And as you recede from 98?

A. As you make it less—

Q. You say blood temperature in the running stream has what effect on the typhoid?

A. The typhoid bacilli increase rapidly at that temperature.

Q. In the running stream?

A. Yes.

Q. Do you mean to say that in the running stream—

A. In the river water, in my laboratory experiments, if you keep that at 37 degrees C.

Q. We are talking now about the water in the stream.

A. The water in the stream is never blood temperature.

7653 Q. Are you right certain of that?

A. I think so—98 1-2.

Q. As you recede from 98 1-2, you increase the opportunity of the typhoid germ to live, don't you?

A. Yes, it lives longer as a general proposition in colder temperature when no other bacteria are present.

Q. Then as you go towards the freezing point he lives longer?

A. Typhoid bacilli can live a long time in ice.

Q. Well then as you approach the freezing point, the typhoid bacillus lives longer?

A. Than at a higher temperature?

Q. Yes?

A. Well, I must modify that. The typhoid bacillus lives best in a high temperature, but it multiples rapidly then and when it multiples, produces poisons to itself.

Q. You are talking about the typhoid in the laboratory?

A. Yes.

Q. We are talking about it in the running stream now. If you can draw any conclusions whatever from your laboratory experiments as to the conditions and changes that take place in the running stream, that is what I am after right now. Now I understood you to say a while ago that the typhoid fever

bacillus did not multiply in a running stream, or in sew-
7654 age, and that the only place that he did multiply so far as you know was either in the human system or in some preparation or medium that had been prepared for it?

A. No, but in pure water—it can multiply in pure water in a favorable temperature. If the temperature is blood temperature and the water is pure, and there are no saprophytic bacteria present to overgrow it, then it can even multiply in water.

Q. Now do your experiments show that?

A. Yes, sir.

Q. Professor, you stated in your direct examination that at the Western Avenue bridge, out of 13 specimens you found colon bacillus present only nine times. Bearing in mind the fact that the liquid at this point is very rich in sewage, and that sewage is extremely rich in colon bacilli how do you account for your failure to detect this germ oftener?

A. The explanation of that would be there were innumerable other saprophytic bacteria multiplying at this place, for which the temperature and the conditions were more favorable than they were for the colon bacillus.

Q. What has become of the colon?

A. In those particular specimens they had evidently either died out or been overgrown by the saprophytic bacteria.

7655 Q. What do you mean by overgrown?

A. Multiply more rapidly — the saprophytic bacteria multiply more rapidly at that temperature than the colon bacillus.

Q. Then you could not detect the colon bacilli in those samples?

A. No.

Q. Might not the same conditions be true as to the typhoid germ?

A. That is what I always maintained, that the rapid overgrowth of saprophytic bacteria kills out or destroys the pathogenic bacteria, so the same holds true for the typhoid bacillus. The colon bacillus is capable of existing longer with the saprophytic bacteria than the typhoid bacillus.

Q. Now then, in your direct examination—

A. I want to add something yet. And in regard to the colon-like bacteria, there were bacilli enteritidis, which belong also to the colon type. It was also found several times there.

Q. It is not what you designate as a colon, or it would be put in that column.

A. It is one of the colon group.

Q. In your direct examination you stated that in city water drawn from the tap, out of seven specimens you were 7656 able to detect the colon bacillus three times. How did it happen that all these revealed no more colon bacilli in the drainage canal than in Lake Michigan, bearing in mind the fact that the former is practically sewage?

A. The cause of that was, that in the Western Avenue sample that we examined here, we had great numbers of saprophytic bacteria present, which had overgrown the colon types, in the sewage already, whereas in the lake water there was no such overgrowth by the saprophytic bacteria, because the water was very much purer and the colon bacillus therefore had a better chance to grow. In other words the competition between the sewage bacteria and the colon bacillus was not as great as it was in the Western Avenue bridge specimen, otherwise, we should have found the colon bacillus every time.

Q. Then, professor, there were better facilities for self-purification in the sewage than there would be in Lake Michigan, is that correct?

A. That is right for the pathogenic bacteria. The sewage is much more favorable for overgrowth of saprophytes than pure water.

Q. Now then, if you start the sewage out on its journey without giving the saprophytes an opportunity to appear, and as dilution takes place you remove the chances for the death of the pathogenic germs, do you not, yes or no?

7657 A. I couldn't answer it that way for the reason that the sewage itself furnishes the organic material for the growth of the saprophytes. It is the sewage that causes the multiplication of saprophytes, whenever there is much organic material.

Q. Under all conditions?

A. All conditions particularly temperature being right.

Q. Then, as you increase the dilution, you increase the ability for the saprophytes to get in their work?

A. No sir, it is the opposite. As you increase the dilution, you spread the organic material over a larger area, and therefore the saprophytes will not be able to multiply as rapidly and overgrow the pathogenic bacteria which are mixed with them.

Q. Well, that is it exactly; that is just exactly the question that I asked you, or aimed to ask you. As you increase the dilution in the running stream and remove the whole material farther down, you increase the ability of the pathogenic germ to live, do you not?

A. Yes sir.

Q. And if the pathogenic germ should get out into the stream and get free from any saprophytes, or saprophytic influence or effect, they would live much longer than they would if they run their chances in a septic tank? 7658

A. Yes sir.

Q. Professor, is it or is it not a fact so far as you know, that the water of Lake Michigan, or rather to the water of Lake Michigan, has been attributed repeatedly, the typhoid fever from which Chicago has long suffered?

A. Yes sir.

Q. Professor, if it is your opinion that the water is not the direct cause of the typhoid fever in Chicago, is it the general opinion of the physicians in the city, if you know?

A. I do not know what their opinion is, but I wish to say that I do not wish to deny the presence of the typhoid bacillus in Lake Michigan, when there are many cases of typhoid fever in the city of Chicago and when the sewage of such patients is emptied into the lake, but the tremendous dilution taking place in the lake with billions and billions of gallons of water before such sewage can enter the inlets will produce such a tremendous dilution and spread of typhoid bacilli that the one who drinks this polluted water is not liable to be infected directly because only very few typhoid bacilli could be swallowed in this way.

Q. The dilution in the lake would be much greater than in the canal, isn't that true? 7659

A. Yes sir.

Q. And much greater than in the Illinois river?

A. Yes and much greater than in the Illinois river.

Q. Now then professor, what I want to know, you stated that it was your opinion that water was not the direct cause of typhoid fever.

A. The indirect cause.

Q. That it is the indirect cause, is that your position?

A. Yes sir.

Q. I want to know if you know whether or not your opinion is the same as that of the physicians generally throughout the city?

A. The majority of physicians treat the subject in a somewhat like manner. They think when the germ is present, that that is all that is necessary.

Q. In other words they believe in the direct cause?

A. Many physicians are under the impression that one germ is all that is necessary to produce typhoid fever, but bacteriologists are trying to instruct their students as well as physicians in general, that it is not true, and that a large number of virulent germs must be swallowed for infection results.
7660 And further, that not only a great number of virulent germs is necessary to produce an infection, but that the resisting forces of the organism must be reduced.

Q. Now, Professor, if you know, state whether or not it is a fact that the drainage canal was built largely in order to secure greater purity of the water supply of the city of Chicago?

A. Yes sir.

Q. Professor, if I understood you correctly, disease producing germs would disappear more rapidly in a warm mixture than in a colder mixture?

A. In a blood temperature they would not.

Q. That would be a warm mixture?

A. But if you will say in room temperature, yes.

Q. Now if this be true, professor, what effect practically speaking, does the addition of 250,000 cubic feet per minute, of lake water have upon the temperature of the water in the drainage canal? In other words doesn't it have the effect of lowering the temperature, a cooling effect?

A. I think the temperature of the water in the drainage canal is very similar to that in the lake.

Q. And the temperature of the water in the lake is lower than it is in the Illinois river without the lake water?

A. I should judge that the temperature is lower.

7661 Q. The temperature of lake water generally is lower than that of river, isn't it?

A. I should judge it was lower.

Q. Then the addition of 250,000 cubic feet per minute from the lake would have a tendency to lower the temperature of the water in the drainage canal, which you have termed an open sewer, wouldn't it?

A. Yes, sir.

Q. Now that professor, would have a tendency to prolong the life of disease producing germs?

A. The temperature in the drainage canal is such as to allow the rapid multiplication of saprophytes as indicated by the gas production which can be seen in the drainage canal, the large bubbles of gas that arise, and as seen also by the great increase of saprophytic life.

Q. Do those gas bubbles arise since the canal has been opened?

A. Yes sir.

Q. Even though there is 250,000 cubic feet per minute: do they still arise?

A. Yes sir.

7662 Q. But if that deposit or composition of water and sewage has increased to the temperature of the Chicago river, prior to the opening of the canal the reduction of the pathogenic germs and disease producing germs would be very much greater than now wouldn't it?

A. If the temperature was higher there would still be more growth of saprophytes.

Q. Correspondingly a more rapid reduction of the pathogenic germs?

A. Of the organic material and the pathogenic germs.

Q. Professor, may disease producing germs live in ice?

A. Yes sir.

Q. Then might not the germs of typhoid fever be carried from the Illinois river and on into the Mississippi, on floating ice formed in the river?

A. I have no experiments of my own of how long they live in ice but some experiments have been conducted lately that prove that typhoid bacilli die in ice within a certain period.

Q. That is about how many days? Thirty days?

A. Yes less than thirty days.

Q. Do they all die in thirty days?

A. From my experience I would judge that typhoid bacilli could live in ice for thirty days.

7663 Q. Then if the ice made the journey down the river to the intake tower at the chain of rocks in the Mississippi river in thirty days, they would carry the typhoid germs with them, wouldn't they. It would carry the typhoid germs with it?

A. If the germs were still alive it could, and if the ice could travel down in that time. If it could go in thirty days and the germs lived that long. they could be carried there, and be alive under those conditions.

Q. Now professor, assume that during a cold snap, late in the winter, some of the water of the drainage canal containing typhoid germs, is frozen into a block of ice, and that soon thereafter owing to a thaw and a freshet this block of ice or a large part of it is swept as ice over the Bear trap dam and down the Illinois river to Grafton. Assuming further that as it enters the Mississippi river and passes on in it, and after reaching the Mississippi river it gradually melts and mingles with the water of the river, arriving by the time it is completely melted, on the Missouri shore, and the intake tower at the chain of rocks, of the St. Louis waterworks, is it not a fact that typhoid fever germs alive and virulent, derived from this source might as readily enter the intake at the chain of rocks as any other microbe in the Misissippi water?

7664 JUDGE SPRINGER: I object to this question on the ground that it assumes that blocks of ice may be formed and have been formed in the Chicago drainage canal, which is contrary to the facts, for it is known here that the drainage canal does not freeze up.

MR. JEFFRIES: I submit that on account of the additional 250,000 cubic feet per minute, and on account of the fact that it has not been determined what additional flow will hereafter be made, that the experience of the Chicago river which contained only a small amount of water, in comparison with the conditions that will exist in the future, and there is no reason why ice may not be formed in the Chicago drainage canal, and for the further reason that the period or number of years that the canal has been opened is too short to form a conclusion that the water will never freeze in the canal or in the future, and for the further reason that as stated by counsel for defendant the organic and oxygen consuming powers are not now what they were in the Chicago river at the time mentioned by counsel.

JUDGE SPRINGER: I object to this further for the reason that the assumption is based upon the conditions in the drainage canal and not in the Chicago river, and also to the assumption that the water freezes below the drainage canal before it enters the Illinois river, because it is well known
7665 here that the water in the Des Plaines river before it
enters the Illinois river, after receiving the sewage outfall of the drainage canal does not freeze during the winter months, so that there is an absence of ice in the drainage canal and the Desplaines river, as far down as the confluence of the Desplaines and the Illinois rivers.

MR. JEFFRIES: I suggest further that because no ice has been formed during the three years that the drainage canal has been opened is no reason why it will not form in that river in the future.

JUDGE SPRINGER: I object further for the reason that this assumption assumes diminution in the oxidizing power which is contrary to the evidence in this case, therefore I object to the assumption contained in your question.

Q. (Question repeated).

A. In the first place the typhoid bacillus arriving in the drainage canal would have had to pass through the sewers of Chicago and in the temperature of those sewers there would have been such rapid multiplication of the saprophytic bacteria due to the great quantities of the organic material, that in my opinion the typhoid bacillus never reaches the drainage

canal; at least the lower part of the drainage canal and probably not even the upper part of the drainage canal. In my
7666 opinion they are dead when they arrive in the canal, because the sewage in our sewer system is in a much more favorable condition for the growth of saprophytes than the drainage canal. This depends, of course, upon the length of time, the sewage remains in the sewers.

Q. Now professor, assuming that in this ice so frozen, as contained in the last preceding question, there was contained typhoid bacilli?

A. You put them in you mean?

Q. We are assuming that they are in the water before the ice is frozen; that the typhoid germs are frozen in the ice, what would you say then?

JUDGE SPRINGER: At what place?

MR. JEFFRIES: At the place of freezing.

JUDGE SPRINGER: They would freeze in a great many places.

MR. JEFFRIES: Now professor, assume that during the cold snap late in the winter, some of the water of the drainage canal containing typhoid germs is frozen into a block of ice, and that soon thereafter owing to a thaw and freshet this block of ice or a part of it, is swept as ice over the Bear trap dam, and on down the Illinois river to Grafton. Assume further that as it enters the Mississippi and passes on in it, it gradually melts and mingles with the waters of that river, arriving by the time it is completely melted, on the Missouri shore, and at the in-
7667 take tower of the St. Louis waterworks at the chain of rocks, is it not a fact that the typhoid fever germ arriving, frozen in said ice, alive and virulent derived from this source, might not as rapidly enter the intake at the chain of rocks, as any other microbe in the Mississippi river water?

JUDGE SPRINGER: I object to the question for the reason stated in my former objection.

A. There would be a possibility of the typhoid bacillus which has not died in this ice, to enter, of course, the intake.

Q. And be distributed into the water supply?

A. With great dilution of course.

Q. That is true, isn't it?

A. The proposition that a typhoid bacillus could live in ice is true, whether in a river or otherwise.

Q. Assuming professor that the assumptions contained in this question are true?

A. Yes.

7668 Q. We are talking now about the assumptions. Admitting those assumptions are true?

A. Yes sir.

Q. It would find its way to the chain of rocks in St. Louis, and be just as liable to enter into the intake in the water supply of St. Louis as any other microbe in the water.

A. Yes, or it might go any other way.

Q. I believe you stated professor, that you made no examination as to the life of the typhoid germ in the polluted waters of the present drainage canal?

A. No sir.

Q. Professor, not having made any examination as to the life of typhoid germs in canal water, you of course cannot say how long they would live in that water?

A. I have stated my opinion, that when the saprophytes increase in great numbers, the pathogenic bacteria disappear before the saprophytes.

Q. That is an opinion?

A. Based upon experiments.

Q. Laboratory experiments?

A. Yes sir.

Q. Professor, assuming that an examination of the water in
the canal was made for the purpose of determining the
7669 life of the typhoid bacilli, and assuming that they were
found present in the tests at the end of six, seven, eight or
ten days, might it not be possible and is it not altogether probable that they do exist in the flask and have not all perished at that time, and that one may be unable to determine their presence because of the overgrowth of the colon bacilli?

A. Just as soon as colon bacilli overgrow them they disappear. Competition between different bacteria is of such a nature that the overgrowth of one is the cause of the destruction of the other, so I am reasonably certain that when one kind has disappeared and another kind has increased at a tremendous rate, that the cause of the disappearance or the destruction of the one, was due to the overgrowth of the other.

Q. Now then assuming that they would live in experiments in the flask, for five, six or seven days in the laboratory, is it not natural to conclude that they would live much longer in the canal with the water flowing through it at the rate of 250,000 cubic feet a minute?

A. No, the very opposite would be true, because in the laboratory experiments I made, I was not using the seriously polluted drainage canal water, but only river water which has not so much organic material or saprophytic bacteria as
7670 are found in the drainage canal. Even in this much less
polluted Illinois river water they disappear in five or six days, and therefore I judge that the more organic material the more saprophytic life there is, as it would be in the drainage canal, the sooner they ought to disappear. Such experiments have been made with regard to other bacteria, such as the cholera vibrio. Rivers containing great quantities of organic material, cause death of cholera germs in from two to four hours, whereas, the less organic material the longer the cholera vibrio would exist.

Q. Professor, assuming that they do live five, six and seven days in the laboratory experiments in water from the canal, upon that assumption is it not natural and reasonable to believe as a bacteriologist that they would live much longer in the canal itself?

A. I have already admitted that several times, that the difference here between the laboratory experiments and the river or canal, would be this, that in the laboratory experiment the products of the other rapidly increasing saprophytic bacteria would remain in the mixture, while in the river it is diffused.

Q. In the canal proper they are able to take care of themselves?

A. Yes sir. Now whatever influence that these saprophytic excretion products may have upon the growth of the
7671 typhoid bacilli, of course, is not present in the river water
or the canal where these products would be diffused.

Q. Then professor, assume that they would live five or six or seven days in the laboratory tests, how much longer would you say they would live in the canal itself?

A. I couldn't tell because I haven't made that experiment, and I do not know what influence these saprophytic bacterial products have upon the typhoid bacillus in the laboratory experiment. It might hinder or favor their disappearance from the mixture.

Q. And that cannot be ascertained?

A. Unless you had experiments in the drainage canal or in the Illinois river for comparison.

Q. Is it not natural to assume, professor, or to suppose, speaking now from the standpoint of analogy, as applied to the science of bacteriology, that if they live five, six and seven days, in the laboratory samples of the water taken from the canal that they would live ten or twelve days in the canal proper?

A. That may be true, but the very opposite may be true. It might be similar to conditions existing in the river Ganges. Cholera vibrio live longer in the laboratory experiments than they do in this river; so the very opposite may be true also. I have not admitted that this production of the saprophytes, necessarily is harmful to the typhoid bacilli and there-
7672 fore destroy them sooner. It may be that the diffusion of these saprophytic products under normal conditions in the drainage canal, causes a still earlier disappearance of typhoid bacilli.

Q. So then it is only a matter of determination one way or the other?

A. Unless the experiments is made in the canal itself.

Q. In other words, if I understand you right, the increased growth of the saprophytic bacteria in the samples, may destroy the typhoid germ because of the products that they throw off?

A. That's it.

Q. While on the other hand the growth of the saprophytic bacteria in the canal proper, with the addition of the water from Lake Michigan may have a tendency to furnish food for the bacteria, for the typhoid?

A. No, it may have a tendency to carry these saprophytic products off by diffusion.

Q. It may have a tendency to carry these products that the saprophytic bacteria throw off, away from the typhoid?

A. Yes sir, by diffusion in the water.

Q. And it is perfectly natural to believe that, is it not?

A. Yes sir.

Q. Upon the theory that all live organisms have the faculty of making an effort to preserve their own life?

A. Yes sir. This diffusion in water is not dependent upon any faculty possessed by the germ.

7673 Q. It is also true, is it not, that while the various organisms of a pathogenic character that do not grow well in the samples and in the tests, that do not multiply in the natural stream, that if they are confined as prisoners, that the condition of imprisonment will in all probability, have a tendency to destroy the life much more readily than it would if you put them out in a running stream, where they could in that way take care of themselves. Is not that natural and true from the standpoint of analogy as applied to bacteriology?

A. Well, the pathogenic bacteria are unfavorably influenced in the stream by the low temperature of the water.

Q. That is unfavorably influenced by the low temperature as far as multiplication is concerned?

A. Yes sir.

Q. But they are favorably influenced so far as life preservation is concerned, by the low temperature, are they not?

A. Yes, but after all, if they cannot multiply, they cannot produce products.

Q. That is exactly true, but at the same time if the temperature is favorable to the life, conditions will necessarily be favorable for their ability to preserve themselves; isn't that true?

A. Yes sir.

7674 Q. Now professor, assuming that the discharge of the typhoid fever patients in Chicago were deposited into the sewers of the city and assuming that they were thence carried into the Chicago river and thence into the Chicago drainage canal and into the canal mixed with the water of Lake Michigan, and that the water in the canal contained numerous numbers of saprophytes and ordinary water bacteria, to the number of 70,-

000 and frequently as many as 4,000,000 per cubic centimeter, and assuming that it required at least 24 hours for the water to pass from Chicago sewers into the Chicago river and the drainage canal and over the Bear trap dam, and assuming that the flow in the Desplaines river and the Illinois river is actually about 40 miles in 24 hours; how far might a typhoid bacillus travel in the water of the Illinois river, assuming that it did not perish while contained therein, earlier than ten days from the place of deposit. How far would it travel, professor?

A. I don't believe they would travel at all; I think they would be destroyed by the time they reach the Bear trap dam.

Q. Professor, we are assuming now everything in this question, based on an assumption.

MR. DRENNAN: I object to the question upon the ground
that there is no evidence in this case upon which the as-
7675 sumption can be predicated that they will live ten or
twelve days in the waters of the drainage canal.

MR. JEFFRIES: I would like to have counsel for defendant prove that they do not live that long. The respondents admit that they put the germs into the river, the burden is on them to get them out.

JUDGE SPRINGER: We have not admitted that we put them into the Illinois river or the Desplaines river.

MR. JEFFRIES: I submit this hypothetical question is based upon the evidence introduced and is therefore a competent question to ask this witness. It is not a scientific question, but is purely based on scientific investigations. It only calls for a mathematical calculation to answer.

A. According to the rate of the flow which you have given me, this could get down to St. Louis in ten days, at the rate of flow of 40 miles in 24 hours.

Q. And would get as far as the chain of rocks and the intake tower?

A. Forty miles a day for ten days would be four hundred miles and that would be beyond St. Louis.

Q. And if typhoid germs were there and were alive, they would be just as likely to get into the water of the St. Louis supply, as any other bacteria that might be found at the chain
7676 of rocks?

A. If any typhoid germs were in the water after ten days, getting in by any manner or any source, and were alive, they of course could get into the intake.

By agreement of counsel, witness Prof. F. Robert Ziet is temporarily withdrawn.

7677 FRANK WRIGHT,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer and testified as follows:

Q. What is your name, residence and occupation?

A. Frank Wright, 2500 Michigan Avenue; Medical student.

Q. Have you at any time taken in any of these lakes or rivers samples of water for analysis?

A. I have.

Q. Please state what you did and when you did it?

A. I took samples from the Illinois and Michigan Canal at Bridgeport, and from the drainage canal at Western Avenue, and from the Illinois and Michigan Canal at Western Avenue.

Q. When?

A. During the period of analyses in 1899 and 1900.

Q. Can you give the dates?

A. The exact dates are given opposite the numbers I think, on the records.

Q. Well, will you please state from whom you received instructions as to the manner of taking these samples?

A. From Dr. John H. Long.

7678 Q. What were those instructinos?

A. A perfectly clean and steriled bottle was taken and this was immersed in the canal, filled, stoppered immediately, the bottle placed in a container and taken to the laboratory immediately.

Q. Did you take them yourself to the laboratory?

A. I did.

Q. Did you follow the instructions that Prof. Long gave you in regard to taking these samples of water?

A. I did.

Q. How long was it, after you took the samples from the water was it until you delivered them to Prof. Long's laboratory?

A. Depending upon the car connection it was anywhere from fifteen to twenty minutes; in a few cases it might have been a half an hour.

Q. You took a street car?

A. A street car in each case.

Q. I will call your attention to the tables introduced in evidence by Prof. Long, beginning with table No. 2, Bridgeport Pumping station and ask you to state whether the samples which you furnished Professor Long were those referred to in that table?

A. They were.

7679 MR. JEFFRIES: I object to the question and I move to strike out the answer because it is incompetent, irrelevant and immaterial, and there is no proof that the witness ever saw this book, and never made the compilations therein contained, and therefore is not able to state that the samples are the same samples that are examined and mentioned in that book. And I move to strike out the testimony of this witness with reference to these samples for the reason that no proper foundation has been laid, and I move to strike out the statement of the witness in which he testified from the publication of the Illinois State Board of Health.

Q. JUDGE SPRINGER: State whether you placed any numbers on the samples that you took from the water, that is, placed any numbers on the bottles?

A. Yes sir, the bottles were delivered to Dr. Long and the numbers were placed on the bottles.

Q. Were the dates placed on the bottles?

A. The numbers and dates.

Q. What else was placed on this label that you furnished to Dr. Long?

A. The place of collection and time.

Q. You may state whether the dates on which you took the samples and the places in the table to which your attention has been called the Bridgeport pumping station, are the same 7680 in the table as those were which you took from that place to Professor Long?

A. Well, these bottles were delivered to Professor Long, and the dates and the numbers and place of collection were placed upon them.

Q. Is that the correct date they were delivered that you see upon them?

A. I have no reason to believe otherwise.

MR. JEFFRIES: I object to the question and answer as not being competent evidence.

Q. What do you know about that?

A. These samples were collected and brought to the laboratory and the dates placed upon them and I believe these dates were the dates on which they were brought.

Q. Please look at the tables following this one in that book which were put in evidence by Professor Long.

MR. JEFFRIES: The book was not put in evidence.

JUDGE SPRINGER: The tables were put in evidence by Professor Long beginning with table No. 2 and continuing with table No. 3.

A. I collected from Bridgeport, Western Avenue, over a period of time between July and December, the 1st of July and the 1st of December, 1899, and during the year 1900 from Bridgeport, and a few samples from the drainage canal, and

7681 from the Illinois and Michigan canal at Western Avenue. And in 1899, over a period from along the first of March until the first of September from the Illinois and Michigan canal at Bridgeport, and at Western Avenue and from the drainage canal at Western Avenue.

Q. I call your attention to the tables put in evidence in this case by Professor Long of samples taken at those places during that time. State whether the dates in the tables to which your attention has been called, and the samples of water referred to there, are the same as those which you furnished Professor Long?

MR. JEFFRIES: I object to the question, as it does not establish the fact that the samples of water taken by this witness, if taken at all, are the samples contained and mentioned in this table.

A. I collected the water. I couldn't tell each and every date, but I collected the water during this period of time that

I have said and this water was delivered to Dr. Long at his laboratory and there the samples passed out of my hands.

Q. And after that——They were delivered between the periods mentioned in these tables?

A. Yes sir, they were.

Q. And after you delivered them, you took no further account of them and know nothing about what became of
7682 them?

A. They were then delivered to Dr. Long, and after that I couldn't say.

MR. JEFFRIES: I move to strike out the testimony of this witness and also the tables as introduced by Dr. Long upon which these samples so taken, or alleged to have been taken by this witness, upon which they are predicated, for the reason that no proper foundation has been laid for their introduction and for the further reason that there is no evidence showing the manner in which this witness took the samples, and therefore the examinations of Professor Long and the results as shown on these tables are incompetent, irrelevant and immaterial.

JUDGE SPRINGER: I understand the witness to have testified since he had been upon the stand, as to the manner in which he took the samples.

Q. What was the manner of taking the samples; what method did you pursue in taking them?

A. I left the laboratory with a bottle that was cleaned and steriled, getting to the place mentioned, this bottle was immersed in the canal, filled, stoppered and brought back to the laboratory in the shortest possible time.

Q. How far did you immerse the bottle in the water?

A. Depending upon the rapidity of the current any where from six inches to two feet.

7683 Q. Did you have any instrument for the purpose of enabling you to immerse it further, or did you use your hands?

A. I used a rope and the length of this rope, which was wet would be the means of telling how far the bottle was immersed.

Q. Did you pursue the same course in each case when you took the samples?

A. Yes sir in each and every case.

Q. In the period of time you have mentioned?

A. Yes sir.

Q. How far from the shore were those samples taken?

A. They were taken as near as possible to mid-stream.

Q. Did you note the temperature of the water or air at that time?

A. The temperature of the water. The air was not taken by me.

Q. How long after you took the water from the canal was it until you reached the laboratory of Dr. Long?

A. On an average fifteen or twenty minutes.

Q. During this time I presume there was no packing of it in ice?

A. No sir, there was not.

7684 CROSS-EXAMINATION, by Mr. Jeffries.

Q. Where do you live?

A. In Chicago, 2500 Michigan Avenue.

Q. How long have you lived here?

A. Eight years.

Q. What is your business?

A. I am a student of medicine.

Q. Were you a student of medicine at the time these samples were taken?

A. I was doing preparatory work at that time.

Q. Did you rinse these bottles?

A. These bottles were cleaned and steriled before giving them to me.

Q. Who cleaned them and steriled them?

A. I couldn't say.

Q. How do you know they were steriled then?

A. They were delivered to me as such.

Q. All you have got is the word of the man who delivered them to you?

A. Yes sir.

Q. Was Professor Long there all the time, every time you got the bottles?

A. Not each and every time.

7685 Q. You had a certain place where they were put and you would go there and get them?

A. I would.

Q. You do not know who had been there before you got there?

A. They were kept under a key and I have reason to believe that no one outside of the laboratory had access to them.

Q. You do not know who steriled them?

A. I do not.

Q. You do not know whether they were sterilized under directions or not?

A. I couldn't say.

Q. How long was it from the time you took the samples until you delivered it to Professor Long?

A. On an average of fifteen or twenty minutes.

Q. Were they put on ice or ice put around them or anything of that kind?

A. No sir.

Q. Do you know whether he commenced his examination of the water immediately after receiving it or not?

A. I couldn't say.

Q. You delivered it to his office sometimes when he wasn't there?

A. If he wasn't there, his laboratory assistants were, the

7686 men who received them.

Q. What did they do?

A. They received this water, the number of it, the date and the place of collection was placed upon it.

Q. But you don't know what they did with it?

A. No sir, I do not.

Let the records show that the same stipulation as to the waiver of signature of this witness be made as that with reference to the signature of the witness W. S. Sayer.

Adjourned until 2:30 P. M. same day, October 6th, 1903.

7687 2:30 p. m., Tuesday, October 6, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination by Mr. Jeffries and testified as follows:

Q. Professor, does the typhoid fever bacillus form spores?

A. No.

Q. If it did, would its longevity in water be greater?

A. Yes sir.

Q. Are there any pathogenic bacteria found in water of streams which do form spores?

A. The spores of anthrax may get into a river.

Q. And the anthrax does form spores?

A. An anthrax bacillus forms spores; whenever it is placed in unfavorable conditions of growth, it takes on the resistant type of the organism which is a spore.

Q. How about lockjaw or tetanus?

A. The tetanus bacillus also produces spores.

Q. How about the staphylococcus?

A. It produces no spores.

7688 Q. And the bacillus enteritidis?

A. It produces no spores.

Q. Now you testified, I believe, that you found anthrax germs and tetanus germs as well as one of the pus formers, in the Illinois river water?

A. Yes sir.

Q. And also the an-aerobic bacillus enteritidis?

A. The bacillus enteritidis, yes.

Q. And of those the anthrax and tetanus form spores?

A. Yes.

Q. Professor, will you state whether or not the spores of anthrax, lockjaw and other highly dangerous pathogenic germs would have a greater resistance and greater longevity in a running stream than the ordinary germs themselves?

A. The spores of all bacteria are highly resistant, and can in the absence of food, exist for a long time without being destroyed.

Q. Now isn't it a fact that the spores of these diseases might readily survive in the Illinois river for many days, weeks, and even months?

A. The spores of anthrax, or of tetanus bacillus might be washed into the river and exist for many months.

Q. Then, professor, if these germs were detected by a 7689 bacteriologist below Peoria, would there be any difficulty whatever in their having had their origin in the Chicago stock yards or hospitals?

A. Tetanus spores are found in nearly all garden earth, and street dirt, and could therefore be washed into a river during any heavy precipitation. Anthrax spores are not commonly found free in nature. They must come from an infected animal or an infected person.

Q. Then the tetanus spores, commonly known as lockjaw —lockjaw may be found and is ordinarily found in street washings and earth?

A. Yes.

Q. Around the gardens?

A. Garden earths, and street dirt.

Q. Then do you know, professor, the ordinary longevity of the tetanus germ, or the tetanus spore, or is there any way by which it may be measured?

A. The spore can live a great deal longer than the bacillus.

Q. How long might the spores of tetanus live?

A. The spore of tetanus can live for months.

Q. For months?

A. Yes.

7690 Q. And then might not the spore of tetanus from the street washings of the city of Chicago be deposited into the drainage canal and from thence into the Illinois river and thence into the Mississippi and reach the chain of rocks at the city of St. Louis, provided it traveled that distance within thirty or more days and be alive?

A. Yes sir, and tetanus spores are found usually in all rivers, so it would not be surprising to find tetanus spores in rivers.

Q. Would there not be very likely to be more tetanus spores deposited into the Chicago river and the drainage canal, coming from the street washings of a city of 1,600,000 people than a city containing 70,000 people?

A. That would not depend upon the amount of people at all; it would depend upon the amount of earth that enters the river, because the spores are found in earth and not in sewage.

Q. What earth is more likely to contain those spores?

A. Garden earth, and street dirt.

Q. Then there would necessarily be more street washings in a larger city than a small one would there not?

A. Yes.

7691 Q. And more waste that partakes of the nature of earth in the larger city than in the smaller, would there not?

A. Well, that would be insignificant. The amount of earth that could be washed from the street washings into a river would be insignificant, as compared with the amount of earth that enters that river by heavy precipitations all along the river.

Q. But professor, the addition of the street washings of the city containing 2,000,000 of people to a stream such as the Illinois river, would be considerable, would it not?

A. No, I said it would be insignificant compared with the large area that a river traverses, and with the large amount of washings that that river would receive from heavy precipitations all along the river. It does not depend upon the number of people in a city as to how many tetanus bacilli are in that city, because the people do not contribute to the increase of tetanus bacilli.

Q. Now then, professor, the addition however, of the street washings of the city containing the 1,600,000 people might be the source of the tetanus germ or spore which may be found, or which might exist in that water of the stream at any given point below the city?

A. It might be the source.

7692 Q. But one could not determine from the presence of the spore itself whether it came from the street washings of the city in question or from some other source?

A. No.

Q. So that if a tetanus germ be detected in the water supply of the city of St. Louis, it could not be determined by the examination of the sample of water from which the germ was extracted, that its original source was the city of Chicago or some other point along the Illinois river, could it?

A. No, that could not be determined.

Q. Professor, I will ask you if you are aware that the intestines of herbiverous animals are known today to be a common source of tetanus, or tetanus germs?

A. They may contain tetanus germs.

Q. Has it not been recently discovered that the intestines are a fertile source of tetanus germs, the intestines of herbivorous animals, and has it not been ascertained to such an extent that it is a serious question for scientists today in determining whether or not they thrive better in the earth or whether or not they thrive better in the intestines of the herbivorous animals, such as cattle, and whether or not the intestines of these animals are not better conducive to their vitality, their production and their strength than the soil of the earth?

7693 A. The contents of the intestines of animals as to tetanus bacilli must be mainly due to the foods that have been eaten and that were soiled with earth, or dirt containing those spores, and in that way the tetanus bacilli may be found in the intestines of those animals.

Q. Then, professor, do you mean to say that there is found in the intestines of the animal the spore that was picked up by the animal and taken into its intestines, or has there been an accumulation of spores of tetanus in the intestine of the animal after the germs have been taken into the animal at its mouth?

A. My opinion is that it is simply the germ in the soiled food that has entered the intestine in that manner, foods soiled by street dirt or garden earth.

Q. Is it your opinion that it remains there?

A. If there was a great increase or multiplication in the intestinal canal of the animal, the animal would die of the toxins produced by the bacillus.

Q. That is your opinion?

A. The toxin would be absorbed and the animal would die.

Q. Might that toxin be drawn off in some other way, or

7694 in someway?

A. It takes such a minute quantity of this toxin to destroy animals that they would need but very few tetanus bacilli to produce a deadly dose.

Q. Might not the animal be immune to the disease?

A. The animal might be immune to the disease also, in that case the bacilli could grow without killing the animal.

Q. Now assume, professor, that the tetanus germ can live and does live in the intestines of the animal and that it multiples in the intestines of the animal?

A. The immune animal?

Q. The immune animal; and assume that the excreta of the animal, the offal of the animal containing these germs, is deposited into the drainage canal, at Chicago, state whether or not, in your judgment, it would be reasonable to expect those germs to pass down the river a great distance before they perish?

A. Tetanus spores can exist for a long time without being destroyed, under all forms of unfavorable conditions.

Q. And under all forms of unfavorable conditions?

A. Yes.

Q. Now have you any approximate idea as to their length of life?

7695 A. No, I have no definite ideas, although I would judge that the longevity of the tetanus spore may amount to months.

Q. To months?

A. Yes.

Q. Professor, what is the size of a tetanus spore?

A. A tetanus spore is about one-fifth to one-sixth the size of the bacillus.

Q. And how do they compare in size with the ordinary water bacteria?

A. It is about—water bacteria? Well now, which one? Water bacteria vary a great deal.

Q. Is it as large as the largest of water bacteria?

A. No, it is much smaller.

Q. Is it as small as the smallest water bacteria?

A. It is slightly larger than the smallest water bacterium. The usual water bacteria are larger than tetanus spores.

Q. Can you observe them with the naked eye?

A. No; you cannot see any bacteria or their spores with the naked eye.

Q. Assuming, professor, that the cattle industry of the city of Chicago averages a daily slaughter of from 15,000 to 20,000, from one end of the year to the other, and assuming that in the intestines of those cattle there is a large number of tetanus germs, active and alive, and assume that a considerable 7696 portion of those germs after being removed from the intestines find their way by the washings of the slaughter houses, into the Chicago drainage canal and that within thirty days, or from thirty to sixty days they find their way into the waters of the Mississippi river at the chain of rocks, is it not possible and is it not probable that those germs will find their way into the water supply of the city of St. Louis, and is it not as reasonable to believe that they will so find their way into the water supply of the city of St. Louis, as it is to believe that any other water bacteria will find its way into the water supply of the city of St. Louis, after it has reached the Mississippi river at the chain of rocks?

A. Yes, that is true, but tetanus is not produced by swallowing the germ; tetanus is produced by inoculation subcutaneously, in the form of a wound, not by swallowing.

Q. Professor, assuming that the tetanus germ is there and in the tap, being supplied in that water from the Mississippi river, and that one of the tetanus germs coming from the slaughter pens referred to in the preceding question—a citizen of St. Louis who cut his finger, and placed it under the tap might not that tetanus germ inoculate the finger?

A. No. In order to inoculate, tetanus bacilli must enter the deeper parts of the skin, where there is no air, other- 7697 wise this germ cannot multiply. Tetanus spores or bacilli are strict an-aerobic bacteria, they will only grow in the absence of oxygen, and therefore it is necessary that the germ enter the deeper portions of the tissues in order that it produce a growth and an infection with resulting tetanic convulsions.

Q. Might not a boy shoot his wet finger with the wad of a toy pistol and produce tetanus?

A. If the skin has been simply moistened with the water containing the tetanus spores, and the wad enters the finger—it is possible for the one or two tetanus germs in the water to enter the deeper parts of that finger, but it is still questionable whether one or two germs would be sufficient to produce an infection, because here again numbers are as essential as they are in all other infections.

Q. Assume, professor, that a citizen of St. Louis should step on a tack or a nail with his bare foot, turn the water from the tap into a receptacle of some kind containing the tetanus germs, and that germ should enter the point where the nail caused the wound on the foot, state whether or not it might not produce tetanus?

A. No. The reason is this, it is a well known fact that the rusty nail is more dangerous in producing tetanus than the clean nail, because in the crevices of the rust, as the nail is entering the skin, is found dirt and tetanus spores.

7698 Q. There was no rust or anything assumed in this question?

A. But it explains the condition here. In withdrawing the nail you leave some of the rust, and with it the dirt and the tetanus spores, in the depth of the wound, where the conditions for growth and multiplication of an-aerobic bacteria are favorable. Now, in the clean nail the spores and the dirt is wiped off as it enters the wound and therefore bacteria remain near the surface and cannot grow. Therefore in a puncture wound, such as you mention it, in the nail wound, the characteristic nail infection by tetanus would not occur if the nail had been free of tetanus spores, by simply washing the external wound with water containing tetanus spores because the parts have already closed when the instrument has been withdrawn.

Q. Then assume, professor, that the nail is rusty and moistened by the water from a sprinkling cart, drawn from the city supply, that has just passed by?

A. Then if that water contains tetanus spores, then they may be alive to be wiped off in the depth of the wound.

Q. And carried into the foot?

A. And left in there as the nail is withdrawn.

Q. Professor, anthrax, I believe you said was a spore producing germ?

A. Anthrax can either be found as a bacillus or as a spore.

7699 Q. What is the size of the spore of anthrax?

A. The spore of anthrax is about one-third to one-fourth the size of the bacillus.

Q. How does it compare with the tetanus spore?

A. It is usually larger, but it varies a little in its size.

Q. What, generally speaking, is the source of the anthrax germ and spores?

A. The source of anthrax is always an infected animal that has had the disease, the bacilli are found in great numbers in the blood of the animal that dies of anthrax, also on the hair of the infected animal and in the discharges.

Q. May it not be on the hair of those animals that have not had anthrax, by their coming in contact with those that had?

A. Yes.

Q. Suppose, professor, that an animal that has been in contact with another animal infected and sick of the disease of anthrax, and assume that that animal coming in contact with the animal affected with the disease or sick of the disease, would obtain the germs of anthrax in its hair, and assuming that that animal obtaining the germs of anthrax by getting in contact with one sick of the disease should be shipped to the city 7700 of Chicago, and slaughtered in one of the slaughter houses of that city, and with the washings of the hair and of the animal passing from the slaughter house into the sewer, and from the sewers into the canal and from the canal into the Illinois river and from the Illinois river into the Mississippi in from thirty to ninety days, state whether or not when those anthrax spores or bacilli reach the city of St. Louis, within from thirty to ninety days, they would be alive.

A. Such a condition is excluded by government inspection here in the city, where all anthrax infected animals as well as other infected animals are destroyed.

Q. Do you know professor, whether the government inspectors examine the hair of each animal that is brought into the slaughter houses or stock yards?

A. If the animal had the spores or the bacilli of anthrax, on its hair, it would be also very liable to be ill of the disease of anthrax. Therefore, if it should reach the slaughter house, it would soon be known.

Q. That is if it had the disease?

A. The disease is rapidly fatal in animals; it is a very pathogenic germ to animals and produces death very rapidly.

Q. Professor, aside from any government inspection, taking the assumptions which I have laid down in the question, to be true, what would you say as to whether or not those germs of anthrax would be alive and vigorous when they reached the city of St. Louis on the Missouri shore? 7701

A. Such a condition would produce immediately a general epidemic of anthrax, amongst all the cattle.

Q. Amongst all the cattle where on the Missouri shore?

A. Wherever the infected animal reaches.

Q. You mean where the animal reaches, or where the infected material reaches?

A. You spoke of an infected animal reaching the stock yards.

Q. Now I am assuming that that animal was slaughtered, and that the washings of the hair and of the animal got from the pens, and the slaughter house into the sewers, carrying with it the germs of anthrax, and that those germs within thirty days reached the Missouri shore in the Mississippi river, state whether or not those germs would be alive and active?

A. They would, if they were spores.

Q. State what effect, professor, they would have upon stock drinking the water and at the same time taking into their system with the water, the germs of anthrax?

7702 A. They would if numerous enough and virulent, produce anthrax in susceptible animals, the fact, however, remains that such animals could not pass inspection here.

Q. Now professor, you say that you found anthrax in the Illinois river. Do you know whether that germ of anthrax or spore of anthrax, whatever it was, that you found came from Chicago or from some other source?

A. No, I do not.

Q. It may have come from Chicago, may it not?

A. There must have been spores, else I probably would not have found them virulent any more, or not found them at all.

Q. But it may have come from Chicago, may it not?

MR. DRENNAN: Objected to as to what may have happened.

A. It may have come from anywhere above the place where I found it.

Q. In other words, if it came from a diseased animal, anywhere upon the watershed above where the sample was taken from the river, it may have come from that source, it may have found its way there, I mean?

A. It may have come from anywhere above the place where it was found. And it is quite probable that anthrax spores come from either tanneries or cattle sheds. I think the danger of anthrax in our state is not so great from slaughtering establishments as it is from tanneries using imported hides
7703 from China and Brazil which have been known to cause
anthrax. In fact I know of one instance in Wisconsin where hides imported from China and Brazil had infected a river with anthrax spores.

Q. But still it was the hide of a herbivorous animal?

A. Yes sir.

Q. Have you any knowledge of the endurance or longevity of these germs in mud, sewage deposits or river swill?

A. An anthrax spore can live anywhere without any food under adverse conditions.

Q. At what temperature will they die?

A. They die at the temperature of boiling water, and will resist even higher temperatures if the heat is dry heat. Moist heat destroy them quicker.

Q. So then they are not liable to perish by any natural causes?

A. No sir.

Q. Will freezing temperature hurt them?

A. Freezing will not affect them.

Q. Professor, are you aware that the germs of anthrax have in fact been found in mud?

7704 A. Whenever they have been found they must have come from infected cattle. They could be found in mud or sewage, may enter the water.

Q. Then you are aware from what you previously said, are you, that this disease of anthrax has been transmitted and that it has been so transmitted in river water from tanneries or the hides of animals?

A. Yes sir.

Q. Professor, do you know whether or not the second outbreak of anthrax in Germany was traced to water?

A. Anthrax bacilli have been found in water occasionally, anthrax spores I mean, and have been supposed to be the cause of infections among cattle.

Q. Through water?

A. That was the supposition because it was known in these cases that infected material had been poured a short distance above, into the river.

Q. Then professor, knowing these facts that you have just stated, what would you say as to the danger from the transmission of anthrax from the stock yards at Chicago to the Missouri shore, in the event that the germs of anthrax found their way to the stock yards of Chicago by the cattle that were put in there?

7705 A. If the anthrax spores get into the river as well as the tetanus spores, they may remain alive. They form resistant spores, which resist all unfavorable influences, such as unfavorable temperature and lack of food, and therefore can remain alive for longer times. Both of them, in order to produce infections, are usually inoculated subcutaneously in man and do not produce infection by swallowing.

Q. That is the tetanus?

A. That as a rule also holds true with anthrax, although cases of intestinal anthrax have occurred.

Q. Now professor, assuming that to be true, the question and the answer just stated, what effect would those anthrax germs have upon herds of cattle that drink water containing anthrax germs on the shore of the Mississippi river below the entrance of the Illinois river into the Mississippi?

A. In that case if they drink large enough quantities of virulent anthrax spores, it would be possible that the animals would develop intestinal anthrax.

Q. Professor, in view of your last answer, what examinations have been made with reference to the determination of how many spores of anthrax are necessary to infect an animal with that disease?

A. I think very little is known with regard to that, very little definitely. The infections where they have occurred 7706 have been of such a violent character, and the infectious material has been in such a large quantity that it was not surprising that large herds of cattle were infected.

Q. But professor, this source of that great infection which you spoke of, must have originated with one spore in one centimeter of water that the first animal infected drank, and that animal in turn infected the whole entire herd?

A. One spore per cubic centimeter is quite a good many bacteria in a liter of water.

Q. Assuming that there was but one spore passing into the intestines of the animal first made ill with the disease, is it not likely that the infection of the entire herd came from the one animal first infected, and might not that have happened?

A. Here the same general rules hold true, with regard to the number of bacteria necessary to produce an infection. From my laboratory experiments with anthrax, in which I regularly use that germ for class experiments, I must say that I have frequently infected guinea pigs, small animals, which are very susceptible to anthrax, and they usually died promptly in 24 to 48 hours with a general infection, but I have also frequently infected guinea pigs with small quantities of living anthrax 7707 spores and they did not die.

Q. Have you any idea as to the virulence of these anthrax germs?

A. Evidently the virulence here must have been decreased, but sometimes I found that the germs were virulent, and that certain animals would recover and others would die, so that the virulence alone also does not explain it.

Q. Then you assume the same position in reference to anthrax and the direct infection as you do to the typhoid bacilli?

A. The indirect infection must be a more frequent source of infection on account of the large numbers of germs that may be formed in favorable culture media, whereas the few individual germs diluted and distributed over large areas of water drank by cattle might not produce the infection.

Q. No, but here is the proposition, professor, do you maintain that anthrax—that there is no direct infection, the same as you maintain that the typhoid germ when applied to the human system, that there is no direct infection?

A. Yes, with regard to rivers and lakes, I think that is the proper position to take.

Q. In other words, your position is; that one anthrax germ will not produce the disease if taken into the intestines of an animal?

7708 A. That's it.

Q. Now then, professor, have you any conclusive evidence that it will not?

A. I have those mentioned in the laboratory, on guinea pigs.

Q. I will ask you, professor, if it might not be true that there are certain conditions pertaining to the intestines of the animal that when a spore is introduced into it, it operates as a media and produces a culture and one culture after another until the animal becomes sick of the disease?

A. Yes, if it becomes infected, but that is the very problem, that infection doesn't always take place, due to the resistant forces of the organism which destroy these germs, even large numbers of them.

Q. If the system of an animal be in a certain condition, is it not likely that the germ of anthrax, the spore of anthrax entering into the intestinal cavity of the animal, that the conditions may be favorable for its multiplication untii the animal becomes sick of the disease?

A. The conditions may be favorable, or may be unfavorable to the infection.

Q. In other words, that is the proposition which the science of bacteriology has as yet been unable to investigate or explore, is it not? 7709

A. What problem?

Q. The conditions that take place inside of the intestinal cavity of the animal after the disease spore or germ has been introduced into it?

A. We know in a general way—

Q. Has it been investigated?

A. Yes, in certain ways.

Q. Now in what way?

A. We have determined that if we reduce the resistant forces of the animal, for instance by destroying the red blood corpuscles, that germs will prove much more infectious, even if the germs were attenuated, and we have found that large numbers of highly virulent germs, introduced into an animal which was resistant, did not produce infection.

Q. Then if the animal be run down, not properly fed, or be ill with some other disease, might not its system be in the condition to produce anthrax if the germ of anthrax is introduced into the system?

A. With a decreased resistant force even smaller numbers of pathogenic bacteria would probably produce an infection, which in the healthy animal would produce no infection.

7710 Q. And aside from all of our opinions and our beliefs on the subject, professor, it may be may it not, that there is a certain condition in the animal itself, that if the germ of anthrax is taken into its system, that it will produce the disease of anthrax in the animal?

A. That condition would be the reduced resistant force.

Q. That it may exist?

A. That may exist with the reduced resistant force of the animal.

Q. Professor, what can you say with regard to the life of pathogenic germs in the soil of the earth—pathogenic microbes in the soil or the earth?

A. The life of pathogenic bacteria in the soil will be somewhat similar to that in water. It would depend entirely upon the number and kind of other bacteria that might be present there and their rapid multiplication. Probably they would exist a little bit longer in soil or earth than they would in water that was rich in organic material.

Q. Then such microbes live longer in the soil and earth, do they not?

A. They could live upon the surface of the earth, dependent on competition and overgrowth of other bacteria for which the conditions for growth are more favorable. They could live

for some time in the dried state, because there would be
7711 nothing to overgrow them.

Q. Would they live longer in lumps of earth or mud or masses of fecal matter than when suspended in water or sewage?

A. When they are in masses of fecal matter you will have again the great number of saprophytes and intestinal bacteria present which grow much more rapidly at the temperature of the air, and would overgrow pathogenic organisms which are of a slower growth and cannot multiply at that temperature to any extent, at least not as rapidly as the colon types and saprophytes.

Q. Professor, are there any intestinal diseases, the germs of which are liable to grow in sewage or polluted rivers, whose spores are more resistant than those of typhoid fever?

A. I have mentioned those which are highly resistant by means of forming spores, that is the anthrax spore and the tetanus spore, but as to non-spore bearing bacteria or non-spore bearing pathogenic bacteria their resistance in water is subject to the overgrowth by saprophytic bacteria, and water bacteria.

Q. Is it not a fact that the germs of diarrhoea live longer than typhoid germs in water?

A. If you will tell me what kind of germs you mean by the germs of diarrhoea—

7712 Q. Well are there any forms of germs of diarrhoea that live longer than the typhoid germ?

A. It has lately been shown that dysentery and some of the summer complaints of children are due to Shiga bacilli, and I have it from the investigator of this subject that this bacillus dies in sewage in a few hours, so that seems to be much less resistant than the typhoid bacillus. This germ is supposed to produce the summer diarrhoea of children.

Q. That is the Shiga germ?

A. Yes sir.

Q. Does that come from the human intestines?

A. That is found in the intestines in dysentery and in children having summer complaint.

Q. Do you know, professor, of any epidemics of diarrhoea in which the germs of diarrhoea have appeared to live longer than the typhoid germs?

A. The bacteria that are normally [illegible] intestinal tract are all more resistant than the typhoid bacillus and grow much more rapidly and much more easily.

Q. And live much longer?

A. And live longer than the typhoid bacillus.

Q. Now professor, is it possible that other diseases than
typhoid fever or Asiatic cholera can be carried by water
7713 and that the vitality of the germs will be greater in water
than that of the germs of typhoid fever?

A. I answered that before. You spoke of the germs of diarrhoea, but you did not mention cholera. Just as soon as you include cholera then of course I shall have to modify that statement because the cholera vibrio dies as easy as the typhoid bacillus in sewage. I have been speaking of the colon type of bacteria entirely in my former answer.

Q. What I mean, professor, is this: Is there any other disease germ, any disease germ other than cholera or typhoid fever that can be carried by water, with a vitality greater than that of either the cholera or the typhoid fever germ?

A. Yes, the colon group of bacteria, they are more resistant than the typhoid bacillus or the cholera vibrio.

Q. What character of disease do they produce?

A. None, when in the intestine, as far as known.

Q. You cannot tell whether it is diarrhoea or something else?

A. In diarrhoeal diseases we occasionally find that these bacteria are present in abnormally great numbers and in various types.

Q. What bacillus is present?

A. The colon types, and there are a great number of
7714 different bacteria of this colon group, which are all more
or less similar in some respects and dissimilar in other
respects. They have not been sufficiently studied, as to their role in the household of the intestine, or as to their role in the causation of diarrhoeal diseases. In fact the etiology of diarrhoeal diseases, outside of the well known infectious diseases Asiatic cholera and typhoid fever, is still very doubtful, for instance, just to illustrate; the disease known as tropical or Amoebic dysentery is supposed to be due entirely to protozoa, small

animal organisms, and not vegetable organisms, whereas, other men who have studied it just as thoroughly believe that these are only accidental invaders of the intestines, and that the causative factor is a streptococcus, which is also occasionally found in intestinal diseases as well as in health, so we know very little in regard to the true etiological factors of diarrhoeal diseases, very little which has been proven.

Q. And both the protozoa and the staphylococcus may come from sewage?

A. The staphylococcus and the streptococcus may come from the sewage, whereas the protozoa that are found in
7715 cases of so-called Amoebic dysentery die quicker in sewage than bacteria would.

Q. But it may come from sewage?

A. It may come from sewage also. Protozoa or Amoebic dysentery are found in the stagnant waters of the tropics and those who drink of that water simply develop a violent diarrhoea. These organisms are found in the discharges and may even produce abscesses in the liver, the pus containing similar organisms and yet other men under the same conditions have found a similar picture of disease and have found a streptococcus, so that the disease, tropical dysentery, is something whose etiology has not yet been definitely settled.

Q. Now, how about dysentery in this part of the country?

A. Dysentery in this part of the country, is most of it due to the streptococcus and to staphylococcus infections, aside from the great number of bacteria of the colon group, such as the Shiga bacillus, the pathogenesis of which must be still definitely determined.

Q. Professor, how about the hardness and durability of the dysentery germs in water?

A. The streptococcus is a germ that dies very easily; it is one of the most sensitive germs kept in the laboratory
7716 and usually dies under the most favorable conditions in a very short time, in spite of all favorable media that we may provide, in spite of all our efforts, they constantly die. The protozoa of tropical dysentery might live, if they are the causative factors of the disease, they might live in stagnant water at higher temperature, for some time, but they do not

exist in sewage. The Shiga bacillus is rapidly overgrown by other bacteria like a typhoid bacillus.

Q. I will ask you, professor, if it is not a fact that the streptococci germs are not very commonly found in sewage?

A. My experience says No, although I know that other men have found them very frequently. My experience is different from that.

Q. Have they been found professor, by competent observers?

A. Yes, some of the men who have found the streptocci are absolutely competent. And I have also found streptococci in serious cases of diarrhoea occasionally.

Q. Now do you know anything about their life in streams, the streptococci?

A. A streptococcus that is found in the intestine—a streptococcus that is capable of producing a spreading infection, such as it does in septicemia and erysipelas, or as is found in rapidly spreading lymphangitis or lymphadentis, die very easily and very readily under favorable conditions and 7717 much more so in the presence of any other bacteria or unfavorable temperature conditions.

Q. That is with reference to the condition in the laboratory and not in the river?

A. And also with reference to the condition in lake water and river water.

Q. Now how about the staphylococcus that produces intestinal diseases?

A. The staphylococci are frequently found in the intestines, where there is a disease, and where there is no disease at all.

Q. What do you know professor, about their life and endurance in water?

A. The same holds true in regard to their endurance in Lake Michigan water and the river water. The staphylococcus, is capable of growing a longer time on culture media and is more resistant than the streptococcus.

Q. How does it compare, professor, with the typhoid germ in this respect?

A. The staphylococcus is capable of defending itself better against overgrowth by other bacteria than either the typhoid or the streptococcus germs, even against the overgrowth of the colon bacilli, so that in cultures from the intestines even from the excrement of a healthy person, we may find easily colonies of the staphylococcus aureaus, and the albus sometimes if they were present in the faeces.

7718 Q. Now I will ask you professor, if it is not a fact that all these bacteria of the various diseases that we have just mentioned, including the typhoid germs, which have been cultivated in flasks or tubes, and especially upon solid media in laboratory experiments, are much less vigorous, becoming weakened and die more rapidly in water than typhoid germs, and the germs of the various other diseases mentioned, coming directly, fresh from the human body?

A. The germs that come directly from the diseased tissue of the human body are always more virulent than those that we have cultivated for many generations in the laboratory. Otherwise their persistence of life and competition with other bacteria in the mixture do not seem to suffer much. They suffer mainly in the virulence, which is decreased or lost.

Q. Is it not a fact, professor, that they often tend to die out under this cultivation in the laboratory?

A. In cultures in the laboratory the streptococci die out very readily; the staphylococci do not; the colon bacilli do not, and the typhoid bacilli die in three to six weeks, but generally the streptococcus is the one that dies out the quickest on artificial culture media.

7719 Q. So that, professor, some of these products have become invisible by multiplication in the tests and by being removed from generation to generation from the original parent. Would they be in such a condition after a series of tests to be comparable with those that come directly from the human system in respect to endurance?

A. In respect to endurance they would grow just as well in a mixture, whether they were the twentieth generation or the first generation.

Q. But in reference to their longevity?

A. In reference to their virulence after the twentieth generation, if it was injected into an animal, it might not prove virulent, whereas the first generation might prove virulent and kill the animal, but as to the manner of growth and the quality of growth, and their ability to grow, and their ability to defend themselves against other bacteria, there wouldn't be much difference, as long as they are alive.

Q. They are weakened however, in some respects?

A. They are weakened in their virulence in many cases.

Q. And being weakened in their virulence, they would be weakened if put back into a running stream?

A. If they would not produce the death of the animal of course they could also be put into the stream and be
7720 found there without producing any pathogenic effect.

Q. Professor, take the typhoid bacilli of the thirtieth generation as produced in the laboratory; take an equal quantity of typhoid bacilli, coming from a patient sick of the disease, and deposit those two quantities of typhoid bacilli into a running stream, which in point of vitality would live the longest?

A. I think the one that had accommodated itself to grow in artificial culture media for thirty generations, would be the one that would be capable of existing longer than the other, which is still used to its parasitic existence. To illustrate, a tubercle bacillus, as it comes from the body, will not grow at all, or it will grow very sickly even on favorable culture media, and it will do so for five or six or eight or ten generations, and suddenly it begins to grow on all common culture media in such a profuse manner, that a rich heavy growth is seen after 24 hours cultivation instead of a thin barely perceptible scale after 2 weeks of growth, as it originally took. It finally begins to grow like a saprophyte, like a common water germ or like a common saprophyte, showing that it has accommodated itself to the new conditions. Now that germ when placed with saprophytes will have a better ability to grow like they do, and to resist their overgrowth, than the parasitic tubercle bacillus, which will be overgrown by the saprophytic bacteria.

7721 Q. Supposing the temperature of the water into which they are deposited, is as much different, for a saprophytic growth, as it is for those that are taken directly from the patient sick of the disease?

A. The colony of the typhoid bacillus, the thirtieth generation, is no doubt more capable for competition with common saprophytic bacteria than the parasitic typhoid bacillus coming from the human body but when you speak of virulence, then the conditions are reversed. The one from the body may produce disease and the one from the culture may not.

Q. None of which is based on experience?

A. Yes sir.

Q. On experiments I mean.

A. Yes sir, on experiments.

Q. In the laboratory?

A. Yes, in the laboratory.

Q. Professor, you have stated in your direct examination that you have frequently observed various so-called pathogenic organisms in the waters which you have examined. Now have you any reason to suppose that these pathogenic organisms when swallowed by a man in drinking water, would have any effect on the health of that man?

7722 A. They might and they might not. That would depend on number, virulence and resistant forces of the man.

Q. It would depend altogether on the character of the germ, would it?

A. No, it would also depend upon the question: Is that germ still virulent or not?

Q. And would it depend in anywise upon the condition of the man with reference to his health?

A. I will repeat again, first the germ must be present to produce infection. Second, the germ must be in sufficient quantities to produce infection, and third, the germ must be virulent. Fourth, the resistant forces of the organism must be decreased. Those are the four conditions in which infection takes place, so that the simple finding of the germ alone would not mean that infection would take place.

Q. Then professor, it is possible, is it, that any of these germs, if given the proper conditions in the human system, would produce disease?

A. If they were in sufficient quantities and virulent, yes.

Q. Isn't it possible that any one of the germs if given—

if any one single germ, given sufficient conditions in
7723 the human system would produce disease?

A. According to my opinion, not.

Q. Not even if the person is out of order? In other words not well; his physique is run down; his health is run down?

A. Not even then, for the reason that over ninety per cent of the persons dying have healed tuberculous foci somewhere in their body, so that ninety out of every hundred of us are infected with tubercle bacilli and yet we do not die of the disease.

Q. But have the disease though?

A. There are some that have the disease, due to the great number of tubercle bacilli with which they were infected, and due to the reduced resistant forces.

Q. How do you measure the quantity of bacilli that is necessary to produce disease when taken into the human system.

A. That is an unknown factor. That we cannot measure.

Q. Then, if it is an unknown factor, you cannot say whether it would take more than 100,000, 10,000, 5,000, 1,000, 100, 5, 2 or 1 can you?

A. No, I cannot. Those four factors must all be present. The germ must be in sufficient numbers. It is unknown, what is a sufficient number. It must be a large number.

7724 Q. If it is an unknown factor, it may be 1 and it may be 10?

A. No. My opinion is that larger numbers than 1 or 10 or 100 are required even if all the other three factors are favorable for an infection.

Q. Might it not be this way, professor, that the one, if the conditions in the human system are sufficient, if surrounded by proper conditions, would finally produce disease, sickly, though its preliminary course might be run for a considerable time while upon the other hand, if there are a great number of the same character of bacilli that are introduced into the system, that they would more readily and more rapidly produce sickness, and also that the infection of the one bacteria is more liable to be overcome by some organisms contained in the human system, than the great number of them are, and that while one may be overcome, yet there is a possibility always of that one producing more bacilli, and those others, until the patient finally becomes sick of the disease?

A. If that was true, then the human race would have had to die out long ago, because we are continually surrounded by disease producing germs and exposed to infections by food and water with small numbers of pathogenic bacteria.

Q. Now I will ask you if you can state postively that one germ of disease, if given the right conditions in the human system, will not produce disease? 7725

A. I could not state that because that has never been tried by anyone, nor myself either.

Q. And has never been determined?

A. We cannot determine that, because we cannot count the germs; they are too small to be handled.

Q. So that what you say upon the subject is more reasoning by analogy than anything else in the science of bacteriology?

A. Yes, and also upon what you see at post-mortems of persons who have died of the disease and also what you see in infections generally.

Q. Professor, do you recognize any difference in the practical importance of these germs, and anthrax, typhoid fever germs, or Asiatic cholera germs, as disease producers?

A. Yes sir.

Q. Now in what way?

A. They must be present to produce the infection. The germ must be present, first, or the infection will not take place, but the germ alone is not the only condition to produce infection. The other three factors I mentioned before must be present, the number, the reduced resistant force and the virulence.

Q. What I have reference to professor, are colon germs and simple water bacteria, which you have called—

7726 Repeat the question.

(Question repeated).

A. I did not hear the word "difference" before.

Q. What is that difference, professor?

A. The organisms that you mentioned, are the typhoid bacillus, the cholera vibrio, anthrax bacillus and tetanus bacillus.

Q. As to their pathogenic character.

A. Anthrax and tetanus are more resistant by reason of their spore formation and if they enter the water they will exist for a long time without being destroyed, whereas the other two will be rapidly destroyed, so that would be the essential difference.

Q. Now as to their pathogenic character, and not as to their endurance, profesor?

A. They are all pathogenic, if entering the body in sufficiently large quantities.

Q. How about the colon bacillus that is found in the body at all times?

A. The colon bacillus may, if it is swallowed in large enough quantities produce diarrhoea. If it enters the tissues, it may produce a slow infection, a purulent, inflammatory process, in different parts of the body. It is the normal inhabitant of the intestines and contributes to intestinal digestion or metabolism.

7727 Q. Now, professor, I will ask you whether or not you consider the germs of anthrax or typhoid fever or tetanus, Asiatic cholera or dysentery—

A. You mean the streptococcus now?

Q. The germs of dysentery, as comparing in any respect with reference to the severity of the disease which they produce with those of the colon bacilli, and others of a similar character which you have mentioned?

A. Well, if you speak of the dysentery organism, you do not mention whether you mean the streptococcus, whether you mean the Amoebic or tropical dysentery organism or the Shiga bacillus.

Q. I am eliminating tropical dysentery.

A. Well, do you mean the streptococcus or the Shiga bacillus.

Q. I want the streptococcus if that applies to the dysentery that usually occurs in this country and climate.

(Question repeated).

A. The colon bacilli I look upon as the least important in regard to their disease producing qualities.

Q. Then professor, are the bacilli coli communis, the bacilli megaterium, or any other that you have found in the

Illinois river or lake Michigan, to be compared for a moment, practically as dangerous germs, menacing the public health, with the germs of typhoid fever and Asiatic cholera and dysentery?

7728 A. With the exclusion of those you mean?

Q. In other words, are the germs of bacilli coli communis, bacillus megaterium or any other that you have found in the waters of lake Michigan or the Illinois river and described as pathogenic, to be compared practically as dangerous germs, menacing the public health, with those of typhoid fever, Asiatic cholera and dysentery?

A. I have not described the bacillus megaterium under pathogenic germs.

Q. Well, eliminating that bacillus, are any of the bacilli which you denominated pathogenic, and which you found in the waters of Lake Michigan and of the Illinois river, to be compared as dangerous germs with the germs of typhoid fever, Asiatic cholera and dysentery, and in that we might include anthrax and tetanus?

A. Yes. I have described the dangerous and disease producing germs which I found as pathogenic germs.

Q. In point of danger, professor, to the public health, in point of the severity of an epidemic that may be produced by them; in point of their ability to destroy the life and health of people, is there any comparison between the germs which you denominate as pathogenic and found in the waters of lake Michigan and the Illinois river with those of typhoid, Asiatic
7729 cholera, tetanus, anthrax and dysentery?

A. I found tetanus and anthrax, and gave them.

Q. Eliminating those two, tetanus and anthrax?

A. I will say that the colon bacillus when entering the tissues in a large quantity, may produce inflammatory processes, but as to its importance in comparing with cholera and typhoid, I will say that all of those found are less important.

Q. They are practically of no importance as compared with typhoid are they?

A. Oh yes, they are of considerable importance; for instance, they may produce, even some of them which I denominated as non-pathogenic poisons, which swallowed in sufficiently large quantities, may cause intestinal diseases, diarrhoea.

Q. You say a large number of those which you classified?

A. Even of the saprophytes. If you should drink for instance, the products of a number of those non-pathogenic saprophytes, it might produce intestinal disease or ptomaine poisoning, a condition more severe in its effects than that produced by the staphyloccoccus, or the streptococcus.

Q. Then, professor, practically speaking, without reference to cultivating large quantities of them and injecting them under the skin in a chemical way that ordinarly, in every 7730 day life as people move about over the surface of the earth? You have referred to the colon bacillus as a pathogenic germ. Now then, taking all these things into consideration, how is it that you can do this, knowing that it is constantly present, a normal inhabitant of the intestines of healthy persons?

A. Whenever it gets out of the intestines into the tissue, it is pathogenic.

Q. The typhoid germ doesn't ever get out of the intestines into the tissues?

A. It also gets out of the intestines, into the blood, the spleen and into the liver.

Q. It goes all through the system?

A. Yes sir.

Q. You recognize a practical difference between the typhoid bacilli and the colon bacilli?

A. Yes sir.

Q. As disease producing?

A. Yes sir. Colon bacilli in large number in the intestine are normal. Typhoid bacilli in large numbers in the intestine cause typhoid fever.

Adjourned until 10:00 A. M., Wednesday, October 7, 1903.

7731 10:00 A. M., Wednesday, October 7th, 1903. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination by Mr. Jeffries, and testified as follows:

Q. Professor did I understand you to state in your direct-examination that you had discovered the bacillus enteritidis in the Illinois river?

A. Yes.

Q. Now state whether or not this was a bacillus enteritidis sporogenes?

A. No.

Q. In other words, it was not in the shape, in the form of a spore?

A. This bacillus produces no spores. It is not the bacillus enteritidis sporogenes of Klein; it is the bacillus enteretidis of Gaertner.

Q. Then it is not true that a spore bearing an-aerobic bacillus named the bacillus enteretidis sporogenes is very common in sewage of all great cities?

7732 A. Klein has described that in England as very common in sewage.

Q. And that character of bacillus is spore forming?

A. That is a spore forming bacillus.

Q. Has it not been found by others in the sewage of large cities?

A. It has been denied by others, amongst which I will mention that some men,—I cannot think of the names of them, some men thought the description identical with Welch's Bacillus Aerogenes capsulatus, and denied that the organism as described by Klein was anything else but Welch's bacillus aerogenes capsulatus.

Q. And that was not spore forming?

A. That was not spore forming.

Q. Are you sure of that professor?

A. Welch's is not according to his first descriptions of the organism.

Q. Now isn't it true that others have found this particular an-aerobic bacillus named the bacillus enteritidis sporogenes?

A. In sewage?

Q. In sewage?

A. Yes, and have described it as Klein's.

Q. And have found them in great abundance?

A. In great numbers, they claimed.

Q. With spores?

A. Spores.

7733 Q. Now professor, is it not also true that its spores are very abundant and very resistant?

A. The spores of that organism, as all spores of bacilli, are all very resistant.

Q. That is a pathogenic bacterium, is it not?

A. That may produce disease.

Q. Is it not pathogenic professor in the same sense that other bacilli that you have found in the waters of Lake Michigan and the Illinois river are considered by you as pathogenic?

A. I know by Klein's description that when injected into the peritoneum of the Guinea pig, that it may produce here a septic peritonitis. I have no personal experience as to its pathogenic character in animal or man.

Q. Is it not commonly described by bacteriologists as a pathogenic germ?

A. I think not. You mean its pathogenic effect to man?

Q. No, we are speaking of it now as a pathogenic germ, in other words, we are classifying bacteria found in water. Now we want to know whether or not bacteriologists would class this bacillus enteritidis sporogenes as pathogenic, along with the colon bacilli and others of like character?

7734 A. That is where I would class it, in its pathogenic effect,—with the class of the colon group.

Q. Then you would class it with the others that you discovered in Lake Michigan water and those that you discovered in the Illinois river, except the anthrax and tetanus. In other words, you would put it in the same class, except that before you made the classification you would withdraw anthrax and tetanus?

A. Yes. I would want to modify that a little. As to its pathogenic effect, I would put it with the class of the colon group of bacteria.

Q. Now professor, do the colon bacteria form spores?

A. They do not.

Q. Do they produce spores?

A. They do not.

Q. State professor, if you know the longevity of this particular bacillus, enteritidis sporogenes?

A. It will, like all spore bearing bacteria, be capable of existing in the spore form for a long time, in water, earth and air.

Q. Would it live in the spore form for months?

A. Yes sir.

Q. Then it is very resistant, is it?

A. It is.

7735 Q. Could it travel from the sewers of Chicago, through the drainage canal, the Illinois river and the Mississippi river to the intake at the chain of rocks at St. Louis, under any conditions—likely to travel between these cities under existing conditions?

A. Spores can exist for months.

Q. Therefore they can find their way to the chain of rocks?

A. Therefore, if in months they should get down there, they would still be spores and alive.

Q. Do you know anything as to the size of these spores of this particular organism?

A. They are oval, and about one-fourth the size of the micro-organism. They vary in diameter; some are larger, some are smaller, slightly.

Q. How do they compare in size, professor, to the spores of anthrax and tetanus?

A. Oh, there is not much difference.

Q. Similar in size?

A. Yes.

Q. You can't observe them with the naked eye?

A. No; you cannot see even the bacteria with the naked eye. This is much smaller.

Q. They are much smaller that what?

A. Than the bacteria.

Q. That is the ordinary water bacteria?

A. Yes.

7736 Q. These spores are much smaller than the ordinary water bacteria found in the water?

A. Well, to give you an idea; they are about one-fifth the size of an averaged sized bacillus.

Q. Water bacillus.

A. Yes. In a tetanus bacillus, the spore is about one-fifth the size of the whole bacillus.

Q. Of its own bacillus?

A. Yes.

Q. And that is also true with reference to this particular germ?

A. With reference to the spores of all bacilli.

Q. Of all bacilli?

A. Yes sir.

Q. So then it is a more difficult matter to detect the spore than it is the germ?

A. No, the spore is detected easy enough; it is a glistening, white body, so that if there are many spores in a culture they are easily found, very easily, in fact just as easy as the bacteria.

Q. Professor, if you should find this particular spore or organism in the water that you were examining, along
7737 with the colon bacilli, and those of like character, it would
have some effect would it not, upon your conclusions as to the condition of the water examined?

A. If I found large numbers of colon bacteria it would.

Q. And the more of this particular organism known as enteritidis sporogenes, you found, the more unfavorable an opinion you would have of the water?

A. No, that wouldn't make it any more unfavorable. If there were large numbers of different bacteria belonging to the colon class, I would consider that as sewage polluted water.

Q. Then you would consider this bacillus about which we have been speaking, and which produces abundantly, highly resistant spores, pathogenic or a disease producing organism, along with the class of colon bacilli?

A. I would.

Q. Then professor, is it not true that using the term pathogenic in the sense in which you as a pathologist employ it, pathogenic being disease producing germs, they may be and actually are frequently passing from the sewers of Chicago, into the drainage canal and down the Illinois river into the Mississippi river to the Missouri shore, to the intake of the St. Louis waterworks at the chain of rocks?

7738 JUDGE SPRINGER: I think there is a great deal of difference between the movement of the spore bearing and those that are not spore bearing. I think the question should distinguish between the two and therefore I object to the question for the reason that it does not.

MR. JEFFRIES: We have reference to the spore forming germs.

JUDGE SPRINGER: Spore forming germs only?

MR. JEFFRIES: Spore forming germs only.

MR. DRENNAN: Then it is objected to because there is no evidence to support the hypothesis as to the facts.

A. Pathogenic bacteria even if present, may be virulent, and they may be non-virulent. Even spores—

Q. MR. JEFFRIES: Professor, we are not talking as to the virulence; we are talking now of the existence in the water?

A. Of pathogenic bacteria?

Q. Of pathogenic bacteria,—of the spore forming character, about which we have been speaking?

A. It is true that pathogenic bacteria in the form of spores, can exist in the water for a long time, and may be either virulent or non-virulent.

Q. And therefore may pass down the Illinois river to the Mississippi on to the Missouri shore, and the intake of the St. Louis Waterworks at the chain of rocks?

7739 A. Spores may do that.

Q. Professor, state whether or not bacteriologists are in close agreement concerning the longevity of the typhoid bacillus under various conditions?

A. It seems not.

Q. That is, it seems that they have agreed on the—

A. No, it seems not; it seems they are not in close agreement.

Q. Is it not a fact that they differ widely as to the number of days during which typhoid germs may live in water and in sewage?

A. I think that the majority of bacteriologists are pretty well agreed that typhoid bacteria can live but a short time in water, as well as in sewage, and shorter in sewage of course than in water, and that they live the longer in water, the purer the water and the more free the water is from saprophytic bacteria and water bacteria, the longer they live.

Q. But professor, don't they differ widely as to the number of days they may live under such conditions?

A. By widely? I would like to know what you mean by widely?

Q. Well, materially then, considerably. Some experiments showing that they live longer than they do in others?

7740 A. Some men have found that with water bacteria only, they live for twenty days; or that typhoid bacilli live in water twenty days, thirty days, providing the water is not badly polluted by saprophtes. Others have found them to die very much earlier.

Q. We are speaking now of what you would term competent bacteriologists?

A. I believe that all competent bacteriologists are agreed that typhoid bacilli in the presence of large numbers of water bacteria and saprophytes at low temperatures, have no opportunity of existing there more than for a number of days.

Q. Now then you regard those men I understood you to say, as competent bacteriologists?

A. Yes, I regard these men as competent bacteriologists.

Q. And of course all of those experiments were made in the laboratory?

JUDGE SPRINGER: They couldn't be made any place else.

A. That is true, all those men have made their experiments in the laboratory.

Q. And I believe you stated a few days ago that they might live longer in the running stream, and they might not live so long as in the laboratory, in other words, that that point had never been determined?

7741 A. That point has never been determined as to what role the products of saprophytic bacteria play in the rapid annihilation of typhoid bacilli in the laboratory experiments, in the bottle.

Q. Then I understood you to say, professor, that it had not been determined and could not be determined from a bacterial standpoint just what effect the changes taking place in the water by the removal of old and the addition of new, would have upon the bacterial conduct of the water or operation of the water, and the life of the typhoid germ in that water?

A. That is correct. I will admit that it world probably live longer if those saprophytic products were not present, but were capable of being removed. As to the time, I think it has never been determined by anyone what the difference would be between the laboratory experiment and the actual experiment in the river water.

Q. That is under the actual condition of the water?

A. Under the exact conditions of the water. That has not been determined.

Q. You did not undertake to give the number of days that they would live or that anyone found that they would live. I understood you to say that they would live for days?

7742 A. For days, not weeks.

Q. Not one, two, three, four days?

A. I said that reputable bacteriologists had found in the laboratory experiments conditions like those I found in my experiments, and to which I have testified before.

Q. That they would live how long?

A. That they would live for days. I did not say "four,"—I said "for a number of days," because bacteriologists differ somewhat as to the number of days a typhoid bacillus can live in water.

MR. DRENNAN: What was the number you gave, professor?

A. In my experiments?

Q. Yes?

A. In my experiments with river water, the shortest time was five days, when I was unable to find them. In Lake Michigan water the shortest time was in one case where there were many colon bacteria—six days, and in the others where there were many water bacteria, ten days, and the longest that I found them in very pure Lake Michigan water at room temperature, eighteen days.

Q. MR. JEFFRIES: Others have found them longer than that, but whether or not it was under the same conditions, you don't know?

A. The experimenters that I am referring to varied in 7743 their statements from five to thirty days, but it is of course all a matter of conditions,—temperature, etc.

Q. They may have used different methods,—different temperatures?

A. Well, as a general rule with all of them, death was earlier at low temperatures. At higher temperatures the typhoid bacilli even seem to increase a little for some days, and then disappear. In that case it took longer, because they really first increase. In the cold temperature, they never increase. At very low temperature, 10 degrees C., therefore, they were very much sooner overgrown by water bacteria. The majority of experimenters agree that the typhoid bacillus lives longest in sterilized water where there are no other bacteria at all present, anywhere from three weeks to nearly two months and six weeks at least in cultures.

Q. Then professor, state whether or not you know that it has been found alive in the river Thames or in the water from the river Thames for five weeks or even longer?

A. The typhoid bacillus?

Q. The typhoid bacillus?

7744 A. I know in a general way, of some instances where the typhoid bacillus has been found in river water, but those instances are very rare and I cannot recollect the names of those men who have found them, but I will admit in a general way that there are some experimenters who claim that they have been able to separate the typhoid bacillus from river waters, in polluted rivers.

Q. I will ask you professor, if they have not been found to live as long as seventy-five days in river water in laboratory experiments?

A. At what temperature?

Q. I don't know the temperature.

A. It all depends on that. I stated that it depends upon the temperature and other bacteria present, as to how long they can live. The purer the water the longer they may live, and that they may live six weeks in a perfectly sterile water, where they are not destroyed by the overgrowth of water bacteria or saprophytes, so that is a question of competition of bacteria. If the temperature conditions are favorable for one kind they will multiply and wipe out the others, which do not multiply at that temperature.

Q. Or if the conditions are so that the sapropytic bacteria will not multiply, they will live longer?

7745 A. That would be a higher temperature. If river water was placed at a temperature of 37 degrees centigrade then the typhoid bacilli would increase, in fact that is one of the methods now, of finding them in river water. One of the latest and most modern methods is to first enrich the water in disease producing bacteria and hold back the growth of water bacteria and saprophytes by the higher temperature. Typhoid bacilli would multiply at the higher temperature, whereas water bacteria and saprophytes, for which the temperature would be unfavorable, would be held back in their multiplication. So here you have enriched the water in typhoid bacilli and held back the others by temperature conditions favorable to typhoid bacilli and unfavorable to water bacteria and saprophytes.

Q. And vice versa?

A. Yes, the same holds true of course. That only illustrates that it is all a question of temperature with regard to the time that the typhoid bacillus can exist in water, and that it is a question of other bacteria present, and their manner of life at different temperatures.

Q. So that with it all, there is no practical way of telling just how long they will live outside of the laboratory?

A. I think there is a way of telling it outside of the laboratory, how long they will live in the river, but I don't know that that has ever been tried.

7746 Q. There is nothing on the record to that effect?

A. No.

Q. Now professor, I will ask you if it is not a fact that the results of different experimenters differ greatly as to the longevity of the cholera microbe, in natural waters?

A. This is due to the same conditions just mentioned.

Q. And the cholera microbe is subject then to the same conditions as the typhoid?

A. Cholera vibrio have been known to die and disappear from waters after hours. It depended entirely upon the organic material, and the other bacteria present, and then it depended again on the water, the purer the water, the longer they live.

Q. I will ask you if it is not a fact that competent observers have found the cholera germs alive for a period of seven to fifteen and twenty days, and even for three months?

A. In steriled water, yes.

Q. Is it not also true that one observer found it alive after 392 days?

A. Oh, we have in medical literature all sorts of statements. You must not forget that bacteriology is a young science, only 25 to 30 years, and over-enthusiasm has done more harm to it—I for instance, remember with regard to the typhoid bacil-
7747 lus that one man found typhoid bacilli in the gall bladder fourteen years and a half after the patient had had typhoid fever, and they were alive. Well, that is quoted also in the literature and might be quoted by you.

Q. And it might be correct?

A. Well, not according to what I know of the biology of the typhoid bacillus.

Q. There might be something, however, that you do not know about it, isn't that true?

A. I admit it.

Q. I will ask you professor, if you would consider the observer who found the germ of cholera alive in water after 392 days, to be a competent observer?

A. I don't like to discredit any one else's opinion in a science that is just developing, although with our present knowledge of the subject I would not accept that statement any more.

Q. But it is a fact, professor, that competent observers have found the cholera germ able to live in sewage as long as seven to thirteen days?

A. I think that also is a statement that could not be proven to be true by the laboratory experiment, that the cholera vibrio could live in sewage for that length of time.

7748 Q. But there are such cases on record, are there not?

A. Such cases may have been reported.

Q. Have any observers found that the cholera germs live longer in sewage than in pure water?

A. No.

Q. That has never been found?

A. Not to my knowledge.

Q. I will ask you professor, if a competent observer has not stated editorially that the cholera germs live longer in sewage than in pure water?

A. That may all be true, but I think that the laboratory experiments discredit that. For instance, Hankin in the reports in the Annals of the Institute Pasteur, says that cholera vibrio have lived only two to four hours in the presence of great numbers of saprophytic organisms and much organic material, so here we have the condition for death even in a few hours. In sterilized water they can live for a long time and they may even multiply in sterilized water.

7749 Q. Professor, assuming as has been stated by competent observers, that the germs of cholera live in sewage and river water as long as thirteen days; assuming that Asiatic cholera should appear in Chicago, and assuming that the germs of this disease discharged into the Chicago drainage canal through the sewage system of Chicago, state whether or not the germs of this disease would not find their way to the St. Louis water supply entering the intake at the chain of rocks, provided the water from the canal covered the distance to St. Louis within thirteen days?

JUDGE SPRINGER: I object to the question that the first assumption is accompanied by the statement that it is based upon the opinion of competent observers, which statement is in the nature of testimony and necessarily a part of the assumption, and I object to it further upon the ground that it is argumentative in character, and does not present all the conditions which exist in the waters of the drainage canal, the Desplaines and the Illinois rivers, which are necessary to pass a judgment upon a question of this kind.

Q. MR. JEFFRIES: Now professor, I want an answer upon the assumptions contained in this question.

(Question repeated).

A. Taking it for granted that they would live thirteen days?

7750 Q. That's it.

A. If they were not killed before, they would of course arrive there. I wish to add that even if they did arrive there; even if they should enter the chain of rocks intake, we would again have to consider the same conditions which I have mentioned so many times: That is the germs would have to be swallowed in sufficient number, they must not have lost their virulence, and the resistant forces of the body must be reduced because Professor Pottenkofer swallowed fresh bouillon cultures of the cholera vibrio, the Asiatic cholera vibrio, repeatedly, to bring the experimental proof that if the resistant forces were normal, you could not produce Asiatic cholera.

Q. I will ask you professor, if he did not, when he made this experiment have a severe diarrhoea?

A. He did have the diarrohea, but he did not get cholera.

Q. Your last statement professor, is based upon your opposition and your judgment against the theory of direct infection is it not?

A. Not only on that. First with regard to that opinion, that it is an indirect infection, that the germ first gets upon some favorable culture media, and secondly upon the basis of the absolute destruction of cholera vibrio in the sewage-polluted water before it even leaves Lockport.

7751 Q. Now professor, state whether or not in your opinion the condition of the system of the person taking the cholera germ into his intestines, that there can or cannot be certain conditions existing with the human system that would produce the culture and produce a growth of cholera germs and that growth continue until the patient finally becomes sick of the disease?

A. From one germ?

Q. From one germ?

A. In my opinion, no.

Q. Now then professor, might not such conditions exist in the human system, that in some systems the vitality and strength of the organisms of the human being would be sufficient to destroy and throw off these germs, while in other systems, run down and in bad health, in bad condition, that those conditions would be favorable to the increase of cholera germs inside of the human system, and the multiplication of them would occur to such an extent that finally the system of the person would be overcome with the disease?

A. Well, in my opinion it is necessary to decrease the resistant force of the human organism. It is also necessary that the germs be virulent and that a sufficient number of them be introduced to produce the disease. If one or more of these factors is absent the disease is not produced.

Q. Might not the resistant force of the organism of the
7752 patient be sufficient at the time one typhoid germ is taken
into the system, to be unable to overcome the effect of that germ, and such a run down and insufficient condition in the organism would bring about a production of cholera germs, until the patient would be finally overcome by the disease? I want your opinion on that subject?

A. I have given it. Even if the resistant forces of the body were reduced or absent, it is very necessary that a sufficiently large number of virulent bacteria be introduced to cause an infection. It is true that the germ multiplies in the human body, and that this multiplication takes place much better when the resistant forces are reduced but it is also true that this factor of reduced resistant force alone is not sufficient to cause an infection. There must be great numbers of virulent bacteria besides the reduction of the resistant force.

Q. I will ask you this question. I want to get right on this proposition. I want to get your idea. Is it not reasonable to believe that if a large quantity of the germs of cholera when introduced into the system of a well patient, a reasonably well and strong patient, that they would overcome the organisms of that patient, that person, until he became sick of the disease. Why will not one bacilli, or one germ of cholera produce a disease in the run down and worn out system of a man,
7753 when it is injected into the system in that condition, and
does not the scale of infection increase and decrease proportionately as the number of germs are introduced into the system and as the system is built up or reduced?

A. Reduced resistant force is only one factor.

Q. Is that a fact?

A. Besides the germ, there are three other factors, number of bacteria, virulence and resistant force. Pettenkofer has drunk virulent cholera vibrio in great numbers in the bouillon culture. So the factor of resistant force must have prevented the disease.

Q. At the same time he had a severe case of diarrhoe?

A. But he didn't develop Asiatic cholera.

Q. But he had diarrhoea?

A. He had vibrios in the stools, but it is shown thereby that even a great number of the virulent germs is not sufficient to produce the disease when the factor of reduced resistant force is absent. All the factors have to be present to produce infection.

Q. Was it clear that Pettenkofer was run down?

A. No, he was in very good health.

Q. Wasn't he in excellent health?

A. Yes sir.

Q. And because of that excellent health he made the experiment upon himself?

A. He overcame the infection of virulent cholera vibrio
7754 in great quantities.

Q. I will ask you if before he made that experiment on himself he did not diet himself and prepare himself for the test?

A. Not at all, he even took the same food that he took all the time. The only proof at that time that the germ alone was not everything, that the other factors which are recognized today in bacteriology, all played an important part, first the germ, second the number must be great; third, the resistant force of the organism must be reduced, and fourth, the germ must be virulent, and only when all factors are right an infection takes place.

Q. I believe you have stated repeatedly, that typhoid with other pathogenic germs, survive longer in purer water than in the more polluted water?

A. Yes sir.

Q. Now, assuming the dilution of the Chicago sewage should at any time become greater, more water of Lake Michigan being mingled in any way with it, is it not also true that the pathogenic bacteria will tend to survive longer?

7755 A. Yes.

Q. And that owing to the quicker flow, caused by a greater volume of water, the bacteria will be more alive and virulent farther down the stream.

A. It is true that the greater the dilution the longer will be the life of the typhoid bacillus, but at the same time also the greater will be the dilution or separation of typhoid bacilli which entered that water, so that a given quantity of water will also contain a smaller number of typhoid bacilli.

Q. But professor, assuming that they live thirteen days and assuming that it requires 11 days for the water to pass from the sewers at Chicago to the intake tower at the chain of rocks in the city of St. Louis, and assuming further that there is a large volume of water added to the flow through the canal with the same amount of sewage going through as now, I will ask you whether or not there will not be a greater number of typhoid bacteria reach the chain of rocks at St. Louis and be deposited into the Mississippi river than with the less flow?

A. Most of them will be destroyed.

Q. And more of them will live with the increased flow?

A. More of them are capable of living with the increased flow under the assumption stated.

7756 Q. Professor, have you any information as to the number of typhoid germs that are discharged from patients sick of that disease?

A. I have never counted them.

Q. I will ask you whether or not they are measured by millions per day?

A. Some days you cannot find any at all.

Q. And other days?

A. And other days there might be millions, and we do find them.

Q. You can find them almost a million per cubic centimeter some days, can't you?

A. Yes in the urine sometimes we find great numbers of them.

Q. You see millions in the urine at times?

A. Yes, there will be millions found in the urine in 24 hours during certain days. I have never counted them.

Q. That would be a difficult test wouldn't it?

A. Well one could determine the number of typhoid bacilli in a quantity of urine, but I have never done so.

Q. You would have to determine it by an examination of each cubic centimeter of urine, unless they were at the same rate and the same amount all the time?

A. No, we would take it for granted that they are 7757 evenly distributed through the urine, because they are motile and are supposed to move at the same rate all through the urine, so the number in one cubic centimeter is determined and the total number figured out for the entire amount of urine voided.

Q. Not during the entire sickness of the patient?

A. Sometimes they are not found at all in the urine.

Q. Do they not clump together sometimes?

A. They clump together in the tissues of the spleen. In the urine they also clump when a patient becomes more or less immunized.

Q. That is generally at the last part of the sickness?

A. Oh no, that is sometimes as early as the fourth day.

Q. On account of that clumping then, the counts might be too low, might they not?

A. If the patient's serum showed the presence of this immunizing substance, we wouldn't be able to determine by the count how many would be in the quantity of urine.

Q. Professor, does the typhoid bacillus multiply rapidly upon food or vegetables at the ordinary temperature of a room?

A. They can grow, but they do not multiply as rapidly 7758 as they do at blood temperature.

Q. At what—it would multiply comparatively slowly wouldn't it?

A. The multiplication is quite slow in room temperature.

Q. Does it multiply rapidly or readily upon vegetables?

A. On a hot summer day, yes.

Q. How would it be in the cold winter or spring?

A. They wouldn't multiply in the winter.

Q. Nor the autumn?

A. What I mean by the room temperature is the average temperature of a room, 70. At that temperature the typhoid bacilli are capable of growing fairly well on culture media. They do not grow rapidly, but they grow. They do not grow as well as they do at the body temperature, but they are capable of growing at that temperature. Now just as soon as the temperature falls more and more, they grow less, until you reach 18 or 20 degrees centigrade, where they would not grow at all any more.

Q. So that in a refrigerator they wouldn't grow?

A. In a refrigerator at a temperature near the freezing point, they would not multiply at all.

Q. Then professor, on your theory of no direct infec-
7759 tion from drinking water, at what season of the year
should typhoid fever be the most abundant when derived from drinking water?

A. The season has nothing to do with it. If water that contains very few typhoid bacilli should get into the milk and the milk into the household, and the common temperature of a room in the household, even in winter for that matter, should be favorable, the typhoid bacilli can multiply. There will be a culture of typhoid bacilli in that milk, and persons drinking that milk will drink a culture of typhoid bacilli. I realize that the seasons for typhoid fever are the spring and fall and not very much in the summer.

Q. But professor, broadly speaking, the temperature of the weather has something to do with it, has it not?

A. Yes sir.

Q. Then the seasons of the year would have something to do with it?

A. The seasons of the year in which typhoid is most common are the spring and fall.

Q. And not in the summer as you would expect, in the
7760 hottest weather?

A. I have seen typhoid fever all through the summer.

Q. But on your theory, professor, assuming that typhoid fever is always present in the same quantity in the water that is being used, wouldn't it be natural to believe that there would be more typhoid fever in the summer than at any other time of the year?

A. I have also an explanation for that. The reason why there are less cases of typhoid fever in the summer than in the spring and fall is because in the summer the temperature of the water is more favorable to the life and growth of saprophytes, and if any typhoid bacilli do get into the water, they are rapidly overgrown by saprophytes, more rapidly than in the fall and winter when the temperature is low. I realize that my theory is perhaps not quite accepted by some epidemiologists, but I have reasons for it, which are entirely based upon the biology

of the germ, and its behavior when it gets into competition with other bacteria, such as water bacteria and saprophytes, as observed in the laboratory experiments stated. There can be no such great and essential differences between laboratory
7761 experience and the behavior of typhoid bacilli in nature.

Q. Then professor, according to your theory it is not surprising that some of the worst outbreaks of the typhoid fever in Chicago have been attributed to the drinking water, and have come in the spring?

A. No.

Q. And also it is not surprising to you that the great epidemic of typhoid fever at Plymouth, Pennsylvania, which has been universally attributed to polluted drinking water, occurred in March, April and May?

A. No, I think that could be explained on the same ground, that the saprophytes cannot multiply as rapidly when the temperature is low. In the warm summer temperature, the conditions are more favorable for the rapid multiplication of saprophytes, and they will then overgrow the typhoid bacillus, whereas, in the spring and fall there may be much organic material, but the saprophytes cannot multiply rapidly, so the typhoid bacillus has a chance to exist longer. It is not overgrown so soon by saprophytes and may thus reach the milk or food supply and then multiply there.

Q. Then professor, I believe you stated that you realized that your opinions as to the direct infection from drinking water, that in that opinion you are diametrically opposed by many of the pathologists, epidemiologists, bacteriologists and san-
7762 itarians of the world?

A. I don't think I am opposed. I believe that most of the leading epidemiologists agree with me in saying that they condemn a polluted water by inspection, although they have not seen the typhoid bacillus in it but they condemn it on simple inspection when it is found that some contamination has taken place or that the discharges of a typhoid patient may have reached it.

Q. But professor, upon your theory of no direct infection of drinking water, are you not diametrically opposed by many of the leading pathologists, epidemiologists, bacteriologists and sanitarians?

A. I think I am not. I believe that most epidemiologists admit the great role and importance that this indirect infection plays in the epidemics of typhoid fever.

Q. Professor, I understood you to say that you did not believe there was such a thing as direct infection from drinking water?

A. That is perhaps the one point where we differ.

Q. And in that you do differ?

A. I think that I differ there from many epidemiologists.

Q. Now professor, I will ask you if it is not reasonable to believe that the infection of typhoid fever by drinking water, may take place either by direct infection, or by the means and in the manner stated, and believed by you, that is, by in-
7763 direct infection, and that the infection depends largely upon the condition of the system, into which either indirectly or directly the infection is introduced?

A. In answer to that I will state that in view of what I know of the biology of the typhoid bacillus I cannot see that a direct infection can occur, except perhaps under the following conditions: If the excrements of typhoid fever patients containing millions of typhoid bacilli, should get into a well, where there is little water, and other persons drinking that water should develop typhoid fever, then it would seem evident that in that case, due to the great number of bacteria swallowed in that way, there was a direct infection from water. I certainly admit that, but I am speaking here in regard to conditions that exist in Chicago, where a large body of water, Lake Michigan, receives sewage polluted material containing typhoid bacilli, or in the Illinois river water, after the sewage of Chicago enters the drainage canal. Even if no saprophytic life whatever should occur and typhoid bacilli should be able to exist until they reached St. Louis, there would be such a tremendous dilution with billions and billions of barrels of water, and the distribution of the individual bacilli to such extent, that they could not, if they did arrive there, produce a direct infection because their number would be too small and only by finding in milk or food supply and favorable temperature conditions a possibility for multiplication sufficient to produce infection.

7764 Q. But they may under that condition at St. Louis and upon your theory, produce an indirect infection?

A. If they are in absolutely pure water and are not exposed to saprophytic over-growth of any kind as they would be in sewage, the conditions would be like those in a laboratory in sterilized water.

Q. Assuming now as stated by you that they reach St. Louis and get into the water supply, and assuming further that they get into a room at room temperature,and find their way onto some vegetable, or in some media on which they would grow, according to your theory, might not the citizens of St. Louis be indirectly infected?

A. Certainly, that would be an indirect infection.

Q. That is your position?

A. Yes sir.

Q. Assuming now, in the case of Chicago, which you mentioned, that the typhoid fever germs came from Lake Michigan, is it not reasonable to believe that the typhoid fever cases so brought about in the city of Chicago were produced in two ways, first in the manner stated by you, that is, indirect infection; secondly, that by reason of the run down condition of the 7765 system of the patients, after affected by the disease, that it obtained conditions in the system, that the one germ or bacteria grew and multiplied until the patient was finally overcome with the diseases. In other words, might not the typhoid fever cases in Chicago, coming from the water supply of Lake Michigan, or coming from Lake Michigan as a water supply, be brought about in both ways, either by direct or indirect infection?

A. The history of the last Chicago epidemic illustrates better than anything else I know, that my opinion is the correct one, because the district that had the greatest number of typhoid fever cases was the district receiving the purest water from Lake Michigan; in other words was the district that received the water from the Four Mile crib, whereas the district receiving the water from the Two Mile crib, much nearer to the shore, had no typhoid fever at all. The district which had most of the cases of typhoid fever here in the city evidently may have used the water which contained typhoid bacilli in a greatly diluted condition. Now if the dilution of typhoid bacilli had been equal all over the lake, why is it that the people that were drinking the water from the Two Mile crib should not have had typhoid

fever, if it was direct infection, why should they not have had more typhoid bacilli and more cases than the district re-
7766 ceiving the water from the Four Mile crib? The fact was that Hyde Park had very few or no cases of typhoid and the poorer district, supplied with the purest water of Lake Michigan, had all the cases of typhoid fever. In that poorer district the water reached decomposing vegetables, and did get into the milk supply of that locality—these people were too poor to buy ice and keep their various food products in the best condition—

Q. And too poor to boil the water also?

A. And too poor to boil the water also, and the result was that if there was one typhoid bacillus in one barrel of water one could have drank the whole barrel without becoming infected but if that one bacillius happened to reach the milk supply or food materials, and was exposed to a favorable temperature it multiplied and these people then simply swallowed cultures containing millions of typhoid bacilli. Now if it were direct infection by drinking water, why did not the people who used water from much nearer the shore, where there was supposedly much more sewage; why did they not have typhoid fever? Because they were people living under the best of sanitary conditions, using only the best of foods, preventing any multiplication or growth of typhoid bacilli reaching their milk supply or food material by way of lake water, which may have contained them in small numbers, by refrigerators and so on.

Q. Now professor, take this barrel of water containing
7767 one typhoid bacillus which you referred to. Supposing that typhoid bacillus should be found going from Chicago within the life of the germ, should find itself in a barrel of water in St. Louis, in a house with a family, and it should, and in your own way of indirect infection, find itself on some vegetable at room temperature or in some media at room temperature, might not it grow until the whole family would become infected with the disease?

A. It would multiply in any favorable culture medium and favorable temperature; it certainly would multiply and if virulent it would infect those with decreased resistant force.

Q. When it multiplies, it becomes a source of danger to the family?

A. Provided it would be capable of passing through the drainage canal without being destroyed, which in my opinion is impossible.

Q. Now then, professor, you stated that this Four Mile crib supplied the water to the poorer section in Chicago?

A. Yes sir.

Q. Do you know whether or not they were the particular class of people who are run down physically and whose systems are susceptible to infection?

7768 A. Admitting all that, that the poorer districts have people whose resistant forces are greatly decreased, that wouldn't settle the question, because we have in the better district—in Hyde Park, also many people who are run down in general health. If typhoid bacilli were in the water and would have been evenly distributed all over the city, they would have had typhoid fever there also, if direct infections took place by drinking lake water.

Q. Now assuming professor, that the water from the Four Mile crib in Lake Michigan, with all of its immense dilution would produce a typhoid epidemic among people who used that water in the city of Chicago, and assuming that typhoid fever germs lived 13 days in the drainage canal and the Illinois river, and passed from the Chicago river to the St. Louis water supply, would not the dilution in Lake Michigan be far greater than that contained in the St. Louis water supply?

A. I have no means of judging here of the conditions. What I have seen of the immense bodies of water of the Mississippi and Missouri as they mingle, with the Illinois river, it seemed to me so immense that it would compare favorably with the distance from our shore to the Four Mile intake.

Q. Professor, I will ask you this question, if the facilities in Lake Michigan at the Four Mile water crib, are not far 7769 better for the life preservation of the typhoid germ where there is an ability to swim away from all objectionable substances, than in the Illinois, Missouri and Mississippi rivers?

A. Yes sir.

Q. Now professor, taking your theory that there is no direct infection of typhoid fever from drinking water, as granted, and assuming that it is correct, how do you explain the fact that in many epidemics the time which has elapsed between the arrival of the infected water within the city or town has been no more than sufficient for the incubation of the disease, and totally insufficient for any intermediary infection of vegetables, or oysters, or other uncooked foods, followed by the multiplication of the microbes upon these substances, and afterwards by an infection of human beings through the consumption of such foods, vegetables and oysters?

A. In the first place my theory as you mention it, does not deny the possibility of a well water containing a sufficient quantity of typhoid bacilli, if it has a short time before, been receiving a large amount of bacilli and causing direct infection.

Q. How about tap water?

A. Tap water usually comes from a large body, like a
7770 large lake, so that this theory refers to great dilutions as
they would exist in rivers and lakes, and not with regard to wells that have recently or a short time before been polluted with large quantities of typhoid discharges. Secondly, as to the time being insufficient for the infection of food. That is not insufficient at all. It only takes twelve to twenty-four hours for a culture of typhoid bacilli to grow. One or two or three typhoid bacilli will produce millions upon a culture medium in a favorable temperature in 24 hours.

Q. Even under unfavorable conditions?

A. The conditions of temperature must be right. The blood temperature is most favorable. In room temperature the growth would be much slower but even at room temperature, 70 Fahrenheit, it would be possible for great numbers of typhoid bacilli to form, even in six hours. So the time is not insufficient for the production of pure cultures on food.

Q. Professor, wouldn't it be a remarkable fact if they grew in such large quantities on vegetables of every town and city, within twenty-four hours?

A. That would depend on the temperature, how fast it would grow and upon the competitive growth of saprophytic bacteria present upon such vegetables.

Q. Now professor, how do you explain the fact that children appear to have taken the disease at school, workmen
7771 in factories, and many people in places where there is
no food?

A. They take their lunch, and they may take their milk along and the milk-can may have been washed out with polluted water, containing one typhoid bacillus. Again, the same proposition, they take it into a warm school room or a factory room and by the time it has stood there four or six hours, they are drinking a culture of typhoid bacilli.

Q. Then, according to your theory, there would be no necessity for the boiling of the water as used by the school children at school houses, for drinking purposes?

A. Now that is a question of conscience. I will answer it as good as I can. I think under these conditions of extreme dilution that it is tolerably safe, according to my knowledge of the biology of the typhoid bacillus to drink lake water, except perhaps during a bad storm where the sewage itself may be carried out rapidly to the intake channels and is gathered in in large quantities.

Q. Suppose that a storm should take place, and turn the sewage from Chicago as rapidly down the Illinois river as it does out into the lake, what effect would that have, wouldn't it push them farther down?

A. Conditions in lake and river are not the same. If Chicago sewage could reach St. Louis as quickly as the Chicago intake channels, typhoid bacilli together with other bacteria would still be alive, although also extreme dilution would have taken place.

Adjourned until 2 P. M., same day, Wednesday, October 7, 1903.

7772 2:00 P. M., Wednesday, October 7th, 1903. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination by Mr. Jeffries and testified as follows:

Q. Professor, you stated in your direct-examination that in all cases the typhoid fever bacillus rapidly disappears from any water to which sewage is added. Now you stand on that statement, do you?

A. Yes, if the temperature is favorable to the growth of saprophytes or water bacteria.

Q. Professor, if a thimble full of sewage is added to a barrel of water containing some typhoid fever germs, do you mean to say that the germs would for that reason rapidly disappear?

JUDGE SPRINGER: I object to this question upon the ground that it does not state whether the water in the barrel was sterilized or unsterilized and for the further reason that it does not state whether there are other bacteria such 7773 as saprophytes and ordinary water bacteria in the water of the barrel before the thimble full of sewage was put in.

A. If in the barrel there is organic material present, or if the organic material that is added with the sewage, is sufficient to favor the growth of the saprophytes, which are in the sewage, then the typhoid bacilli will be again overgrown. If however, the organic matter is very little,—inappreciable; if it is a very potable, pure water comparatively, then the water will contain mostly water bacteria which can multiply even in the absence of organic material and will multiply and also will overgrow at the temperature of the river or the temperature of the lake, which is favorable to the rapid multiplication of water bacteria. These will also overgrow the typhoid bacilli which will disappear. They will, of course, disappear slower where only water bacteria multiply, than they would if there was organic matter present, and saprophytes.

Q. Now professor, if a thimble full of sewage is added to a barrel of water containing some typhoid fever germs, this barrel of water taken from Lake Michigan at the mouth of the Four Mile crib, do you mean to say that the germs of typhoid fever would, on account of the discharge of the thimble- 7774 full of sewage into the barrel of water cause the typhoid germs to more rapidly disappear?

JUDGE SPRINGER: I object to this question upon the ground that the assumptions stated are not such as pertain to the waters of the Chicago drainage canal, or the Desplaines river, or the Illinois river, and that any answer that the witness might give to this question would be immaterial and not tend to establish any of the issues in this case.

MR. JEFFRIES: I suggest that the question goes to the strength of the witness' qualifications, and the statements that he has made concerning the condition of the Illinois river at Grafton, and in reference to the degree of reliance that is to be placed upon bacteriological experiments, as applied to the bacterial contents of running streams.

JUDGE SPRINGER: In reply to that statement I desire to state that the condition which is assumed, of a thimble full of sewage being added to a barrel of Lake Michigan water is an assumption that is not applicable to any of the conditions with which we are now dealing and cannot be applicable to any of the issues in this case, and for the further reasons stated heretofore, I object to the question and to the answer that may be given.

MR. JEFFRIES: In reply to counsel's objection I will state that if it be true that the mixture of the water from Lake Michigan, with the Chicago sewage is equal to a barrel
7775 of water to a thimbleful of sewage, or in any way approaches a greater pollution, as suggested by counsel, that the question is certainly competent as proof on the main issue involved in the case, aside from the question as to the strength and character and extent of credit that is to be given to this witness as a bacteriologist.

Q. (Question repeated).

A. If the Lake Michigan water in this case did not contain larger quantities of organic material it would not do so.

Q. You are acquainted with the water of Lake Michigan at that point, are you not?

A. Yes, but that varies according to precipitation and winds.

Q. And as that varies, the water in the Illinois river of course would vary likewise?

A. It would vary likewise.

Q. Suppose, professor, that a large volume of comparatively pure water containing typhoid fever germs, such as the water in Lake Michigan, receives a relative small volume of sewage, itself containing typhoid, do you mean to say that this small volume of sewage would cause the typhoid fever germs to disappear rapidly and if so, what do you mean by the term "rapidly?"

A. By the term "rapidly" I mean that typhoid bacilli
7776 can disappear in the presence of large numbers of saprophytes, and much organic material, in five or six days, and as to the proposition, I would say that the drainage canal is nothing but a large septic tank now.

Q. What is a septic tank?

A. A tank containing sewage in all conditions of rapid multiplication of saprophytes, due to the presence of large quantities of organic material; water containing sewage in which sewage bacteria are disposing of the organic material by rapid multiplication, as long as the food lasts.

Q. Has the presence or absence of dissolved oxygen anything to do with the septic operations in sewage?

A. Yes.

Q. Are all sewers septic tanks?

A. Yes, sewers are septic tanks in a measure.

Q. If they are septic tanks, and if a stream such as the Chicago drainage canal is a septic tank, why professor, has it been necessary for people to make large—for large cities to make these vast and extensive improvements towards purifying the water into which the sewage is discharged?

A. Because the people living just below a large city which disposes of its sewage by turning it into the river, had to use such water for various purposes, and the water as thus
7777 polluted with large quantities of sewage, produced a nuisance to those living near to the city which disposes of its sewage in that way.

Q. A nuisance in what way?

A. A nuisance mainly by the stench produced, and by the other objectionable features of living on a river which is receiving sewage.

Q. If it was objectionable on account of the stench, would it not also be objectionable for drinking purposes?

A. Certainly.

Q. And would not those objections for drinking purposes continue long after the stench had left it?

A. It would continue for some distance.

Q. And for some time?

A. Until purification had again taken place.

Q. And that would depend on various and an innumerable number of conditions?

A. All conditions, yes sir.

Q. Are all septic tanks and septic conditions equally favorable for the destruction of pathogenic germs?

A. Pathogenic germs disappear and cannot live whenever there is a rapid multiplication of saprophytic bacteria, at a
temperature which is favorable to the bacteria of sewage,
7778 and of water, and is unfavorable to the rapid multiplica-
tion of pathogenic bacteria.

Q. Professor, if the Chicago drainage canal today is a septic tank, as you term it, what effect has the discharge of 250,000 cubic feet of water per minute from Lake Michigan through that canal had upon its septic operation and septic effect and conditions?

A. As much as I can see, only that of diluttion, and removing some of the objectionable features with regard to stench.

Q. Has it not, on account of the increased flow in the canal over and above what the conditions were in the Illinois and Michigan Canal and the Chicago river, removed or reduced the septic operations?

A. Yes, but the septic operations and the disposal of pathogenic bacteria by rapid multiplication of saprophytes, need not be carried to such an extent as to produce a nuisance, by producing stench. There is no doubt a point between extreme dilution and stench where the same process will go on, the destruction of organic material, by saprophytes, and with it also the disposal of disease producing bacteria, and where at the same time, by dilution by lake water, the other objectionable features,
such as stench, can be removed. The septic operation
7779 might remain complete in the drainage canal even with-
out destruction of the fauna and flora of the Illinois river,
and the animal life, I will say, of the river.

Q. Do you put yourself on record as saying that the addition of 250,000 cubic feet of water from Lake Michigan, passing through the canal every minute, has favored the septic operation of the water in the canal, and the sewage in the canal?

A. No. It has simply done this—

Q. As a matter of fact, professor, has not the addition of the 250,000 cubic feet of water per minute reduced the septic operation?

A. It has by dilution reduced the septic operation, but not stopped it.

Q. Don't you know as a matter of fact, professor, that the addition of 250,000 cubic feet of water per minute into the canal from Lake Michigan, has cooled the temperature, and has injected dissolved oxygen and has in a large sense and to a large degree, practically destroyed septic operation in that canal?

A. All that granted, but the fact remains that the dilution of sewage can be carried to such an extent that no stench is present and that even no algae and no fishes are destroyed, and yet the bacterial impurities are disposed of—

7780 Q. When those conditions exist, it is simply the result of the bacterial operation of the water?

A. Yes.

Q. Without reference to the septic operation, is that true?

A. Yes, sir, the bacterial operation.

Q. Then do you mean to say, professor, that the addition of 250,000 cubic feet of water per minute, passing through the canal, does not reduce the multiplication of your saprophytes, does not in turn reduce the time limit for ultimate destruction of all organic matter that is contained in the sewage of Chicago, and that is discharged into the canal?

A. That is true, but at the same time, it is not of such an effect as to allow pathogenic bacteria to remain, because there are no fish and no algae capable of living in the drainage canal. Therefore the action of saprophytic bacteria upon sewage and organic material in the drainage canal in spite of the great dilution that you speak of, has not been affected, so that I would say that the operation in the drainage canal, even with this large body of water that is turned in, is perfect as far as the multiplication of the saprophytes is concerned and its septic tank action.

Q. Do you take the position that because no fish live
7781 in the drainage canal, that there are no pathogenic germs there?

A. No, I take the position that the dilution is not sufficient in the drainage canal for fish and algae to live, and that therefore as far as the disposal of the sewage is concerned, the addition of the water has not had the effect of allowing the pathogenic bacteria to pass, because the saprophytes are in such immense numbers in this sewage tank as to overgrow them.

Q. Professor, would not the pathogenic germs be destroyed very much more rapidly in the old Chicago river before the canal was opened, than they will in the canal since the water from Lake Michigan has been running through it?

A. The more sewage, the more organic material, and the more rapid the pathogenic bacteria—

Q. Answer my question professor.

(Question repeated.)

JUDGE SPRINGER: You are speaking of the Chicago river or the Illinois and Michigan canal?

MR. JEFFRIES: I am talking of the Chicago river now.

A. The Chicago river was as bad physically as the upper part of the drainage canal is now.

Q. Wasn't it worse?

A. I don't think it can be very well—be worse than the upper part of the drainage canal is now.

7782 Q. But you didn't see it though at the time?

A. Yes, I think I have smelled it.

Q. Before the canal was opened did you see it?

A. Yes, and smelled it.

Q. And even with the addition of 250,000 cubic feet of water per minute, it still smells?

A. It still smells.

Q. I will ask you professor, if it is not a fact that conditions existing prior to the opening of the Chicago drainage canal, when the Chicago river was flushed out into the lake, that there was less liability for pathogenic germs or typhoid fever germs passing with those floods into Lake Michigan, than there is now in those germs passing down the drainage canal into the Illinois river?

A. I think the opposite is true. I think the 30 miles of drainage, canal with all its saprophytic life, is more destructive to the pathogenic bacteria than the short distance of the lake.

Q. Then professor, the sewage of Chicago remaining in the Chicago river for a number of days prior to the opening of the canal, the deleterious matter was removed was it, and if that be true, how is it that that sewage when passing out into Lake Michigan, by means of the flood when the channel of the river was reversed, has produced typhoid fever in Chicago?

7783 JUDGE SPRINGER: I object to the question on the ground of assuming a fact not contained in the evidence given in the case, and that the answer will not tend to establish any issues in this case.

MR. JEFFRIES: I submit that that fact has been shown by the evidence of this witness.

MR. DRENNAN: Well, we disagree with you.

Q. (Question repeated.)

A. I don't know that that was the cause of typhoid fever in Chicago.

Q. Assuming, professor, that that was the cause, and assuming that the flushing out of the Chicago river prior to the opening of the present drainage canal was the cause of the typhoid fever in the city of Chicago. I want to ask you now if the facilities for those typhoid fever germs being discharged into the Illinois river are not far better today than the facilities for their discharge into Lake Michigan were prior to the opening of the canal?

A. No, I think not, for the reason that these typhoid bacilli now would have to travel in the drainage canal thirty miles. The distance from the Chicago river to the lake is not as great, therefore they would not remain as long there.

7784 Q. Assuming professor, that the typhoid germs coming from the sewers of Chicago, remain in the Chicago river for days and weeks prior to the opening of the present canal?

A. They then would be destroyed.

Q. Then assuming that although they remain in the Chicago river for days and weeks, and were afterwards flushed out into Lake Michigan and produced typhoid fever in Chicago, I want to know if, assuming those premises to be true, if the conditions and the facilities for the germs of typhoid fever today, passing through the canal into the Illinois river, are not far better than the facilities were for their living in the Chicago river and passing from that river into Lake Michigan prior to the opening of the canal?

MR. DRENNAN: That is objected to as assuming a condition of facts foreign to the testimony.

A. That condition has not been proven.

MR. JEFFRIES: I suggest to the witness that he answer the question, and I suggest to the counsel that Professor Long did testify that the sewage remained in the Chicago river for weeks and days, and that at storm times, flood times, it flushed out into Lake Michigan.

MR. DRENNAN: I submit that he did not testify that typhoid germs remain in there for days and weeks and then were washed out.

7785 MR. JEFFRIES: I submit that the results on the people drinking the water, is the best evidence on that proposition.

JUDGE SPRINGER: That may be true, but that was not the testimony of Professor Long. He was testifying in regard to the sewage solely.

MR. DRENNAN: They have a right to base a question upon their recollection of the testimony of course.

MR. JEFFRIES: I am willing to stand on my question, and the assumptions made, as having been proven in evidence.

Q. (Question repeated)

A. In the first place the assumption, according to my view is impossible, that the typhoid bacilli can remain for weeks in the sewage polluted Chicago river——

Q. But professor, we are assuming that it does.

MR. DRENNAN: Let him get through with his answer.

MR. JEFFRIES: Yes, that's right.

A. But granted, that they were still alive, they would have even then a shorter way to travel into Lake Michigan, than they would have through the drainage canal and therefore there would be more certainty that they had been alive and remained alive after they once entered Lake Michigan, than they would when they entered the Chicago river, or entered the Illinois river. 7786

Q. But professor, were not the facilities for destruction of the pathogenic germs remaining in the Chicago river, with scarcely no current, for days and weeks, more readily produced than in the drainage canal today?

A. Yes, I think that is true.

Q. That is exactly what I want to get at.

A. In other words the sewage was present for a longer time without any current whatever, and therefore had a longer time to destroy other pathogenic bacteria.

Q. Then to that extent their ability to get into Lake Michigan would not be so great as their ability to get into the Illinois river, by means of the canal, because of having remained in the stagnant sewage of Chicago in the Chicago river, for days and weeks?

A. They would have disappeared in both cases, according to my view.

Q. But assuming, professor, that they got to Lake Michigan in the one case, and assuming that they got into the Illinois river in the other case, now which condition is the most favorable for their reaching the points of destination about which we have been speaking, to-wit, the Illinois river in one case, and the Lake Michigan in the other?

7787 A. Under that assumption, to the Illinois river.

Q. It would be more unfavorable?

A. It would be more favorable.

Q. In what way would it be more favorable?

A. Because the saprophytic bacteria would not be as numerous.

Q. Where?

A. In the drainage canal.

Q. Would not be as numerous in the drainage canal when?

A. You are still questioning on your assumption now?

Q. Yes. In other words, there would be more reason to believe that they would get to the Illinois river than there would to believe that they would get to Lake Michigan?

A. Yes sir, under the assumption made first.

Q. Now professor, assuming that the sewage of Chicago would remain in the Chicago river for days and weeks before it was discharged into the lake or discharged into any other stream, assuming also that the sewage of Chicago is discharged into the drainage canal, with the present flow of water from

Lake Michigan, and that it requires only 24 hours for the water to run from the mouth of the Chicago river at Lake Michigan, to Bear Trap Dam, which condition is the most favor-
7788 able for the destruction and death of pathogenic germs?

A. The one in which the pathogenic bacteria are the longest present, with the saprophytic bacteria—

Q. In other words the best place for their disappearance and destruction would be in the Chicago river then prior to the opening of the drainage canal, would it not?

A. For that distance and that time of flow, yes sir.

Q. Don't you know as a matter of fact, professor,—you stated I believe that you were acquainted with the Chicago river prior to the opening of the canal. Don't you know as a matter of fact that the sewage of Chicago leaves the city much more rapidly now than it did prior to the opening of the drainage Canal?

A. Yes, I think that is the case.

Q. In other words, the sewage of Chicago now does not remain in the river, but by reason of the addition of water from Lake Michigan, it is swept on through into the canal and from there into the river Desplaines, isn't that true?

A. As much as I know, yes.

7789 Q. Professor, a great deal has been said by you about the diffusion of typhoid germs in water by dilution. Have you any evidence where such germs are mixed with sewage, the dilution or distribution of the germ is strictly uniform, or do they not go in eddies, groups, masses or otherwise, and thus become concentrated in some portion of the water, rather than uniformly distributed, or is there anything to be known on that subject?

A. I think very little is known with regard to that, as to their behavior in water, because they apparently by the tremendous dilution, become entirely lost, so that bacteriologists, even with the most modern means, have difficulty in finding them in large bodies of water into which they have been turned.

Q. They may go in eddies and in groups and masses or otherwise, according to floods and freshets?

A. And according to surrounding conditions.

Q. Are they diffused, professor, only in water?

A. No, the typhoid bacillus is a motile bacillus, it has motility of its own and is capable in that way of moving from place to place.

Q. And he will find conditions that will best suit his own purpose?

A. If it is not killed before.

7790 Q. Are not bacteria, suspended bodies in water?

A. Yes.

Q. And are they not subject to all laws which govern the destruction of suspended matter in water?

A. Except when they have motility of their own.

Q. With the addition of the motility of their own, they are subject to the same laws?

A. Otherwise they are subject to the same laws.

Q. Have you made any personal investigation of the behavior of bacteria in a septic tank process?

A. I have not.

Q. Therefore you have no precise knowledge on that subject?

A. No.

Q. Professor, have you made any experiments upon the behavior of bacteria in sedimentation?

A. I have not.

Q. Have you made any personal investigation of bacteria in sediments of river muds?

A. I have not.

Q. Have you made any experiments upon the actual behavior of bacteria in streams or rivers, when exposed to dilution with a view of determining whether or not they move in masses, groups and the like, or are uniformly distributed? 7791

A. I have not.

Q. Then is it not a fact that bacteria are such small forms of suspended matter in water as cannot be possibly diffused uniformly through the water, under dilution, as dissolved material itself or dissolved substances are diffused? That I believe you answered?

A. Yes, with the exception of the motility of some of the organisms.

Q. When you say Yes, you mean you have previously answered it?

A. Yes sir.

Q. Is it not a fact, professor, that the whole matter of diffusion and transmission of the germs and sewage in water is very different under different conditions?

A. Yes, there will be very little sedimentation if the flow is sufficient.

Q. And dilution?

A. There will be very little sedimentation if the flow is sufficient. If the flow is not sufficient, there will be more sedimentation.

Q. Is it not a fact that if the sewage of Chicago or any part of it passes into Lake Michigan, that there is good reason to suppose that owing to the conditions existing in Lake Michigan, its disappearance, if it did disappear is largely due 7792 to sedimentation, and that the facilities for sedimentation in Lake Michigan are far greater than those in the drainage canal and the Illinois river, and that the facilities for sedimentation in the Illinois river and the drainage canal do not in any conditions resemble or compare with the conditions and facilities for sedimentation in Lake Michigan?

A. That is more a question for the sanitary expert. As a general proposition I believe, that it is true, the greater the flow of the river the less opportunities for sedimentation.

Q. As a bacteriologist, professor?

A. That is no doubt true.

Q. As a bacteriologist?

A. That there is more sedimentation in the lake than in the river, with a rapid flow.

Q. And as the current of the Illinois river is increased by an added volume of water, the conditions for sedimentation are changed, and there is less ability and less facilities for sedimentation, added increased current, added volume and increased current than there was prior to the increased current?

A. Yes, the more the flow the less sedimentation; the more rapid the flow the less sedimentation.

7793 Q. You mean of bacteria?

A. Of all suspended substances.

Q. Which includes bacteria?

A. Yes sir.

Q. Can a sewer containing a fluid, suddenly change in composition from hour to hour, even from moment to moment, fairly be regarded as in any degree comparing with the vessel that rests in the laboratory experiment?

JUDGE SPRINGER: For what purpose?

MR. JEFFRIES: For the purpose of detecting its bacterial changes?

A. It can be made as nearly right as possible, except the feature of disposal of products of sewage bacteria, which in the vessel cannot be disposed of by dilution and carried off, but which in the sewage or in the river, would be capable of being disposed of. The other conditions can be made as similar as possible.

Q. Professor, does the sewage ever remain in the sewers of a city, a modern city for any such length of time, or for any great length of time?

JUDGE SPRINGER: I object to the question unless it locates Chicago or St. Louis.

A. It probably does not remain very long there, although
7794 I have no idea at all of how long it does remain in the sewers of Chicago.

Q. Does it remain from five to ten days?

A. It might; I don't know.

Q. Yet you have drawn comparisons without knowing the length of time sewage remains in the sewers?

JUDGE SPRINGER: I object to the question.

Q. MR. JEFFIRES: In other words, comparisons between your experiments and the conditions existing in the sewers of large cities?

A. I have not. I have made comparison experiments in the laboratory, as to how long typhoid bacilli live in Lake Michigan water and how long it lives in the Illinois river water, but not how long it lives in the sewer.

Q. Professor, if sewage can be held in sewers for a sufficient length of time to remove all deleterious and disease producing germs, why is it that large and populous cities have constructed plants at enormous expenditures to purify their sewage?

A. For the reason to reduce the pollution of their water supply by sewage, I take it, and for the reason that it is a nuisance for those who live near by and are obliged to use this water.

Q. Professor, do you believe that all disease producing 7795 germs have been destroyed before the sewage leaves the sewers in the city of Chicago?

A. No sir, I never stated that.

Q. Now professor, if they are not destroyed in the sewers, assuming that it takes a certain number of days to destroy them —or is it possible that they are all destroyed in passing from the mouths of the sewers of Chicago to the canal through the Bear Trap dam?

A. It is possible.

Q. Assuming also that they are discharged into a diluting substance of 250,000 cubic feet of water a minute, after they leave the sewers into the canal and Chicago river?

A. It is possible, except spores.

Q. Well, now I don't understand the answer.

A. You spoke of pathogenic bacteria and I said it might be possible that they would all be destroyed in the drainage canal except perhaps the spores.

Q. Now upon the other hand, unless they would all be destroyed within two days in the sewers, and they only remained in the sewers one day, state whether or not they would be destroyed after being discharged into the canal at the end of the first day, passing down the canal at the end of the second day, this immense dilution considered?

7796 A. If it takes 24 hours to go down there, they might not be destroyed at the Bear Trap dam.

Q. And if they would live three days in the sewer and only remain there one day, then the chances are that a great many more of them would get to the Bear Trap dam and be discharged into the Illinois river at the end of the third day than they would at the end of the second day, isn't that true?

A. Yes sir.

Q. And so on, the ratio increases, if they will live ten days in the sewer, then there are greater possibilities and probabilities of their passing further down the drainage canal and on still farther down the Illinois river, isn't that true?

A. Yes sir.

Q. Assume, professor, that it has been demonstrated by bacteriologists that typhoid germs will live in sewage five days, and assuming further that these bacteria of typhoid remain in the sewers one day, that is in the sewage of Chicago one day, that at the end of the first day they are discharged into the drainage canal where they meet 250,000 cubic feet of water per minute; state whether or not that increased dilution would have any effect upon the longevity of the typhoid bacillus?

7797 A. I have already said that the more water, the more pure water the longer they would live.

Q. Then if they lived five days in sewage, after being deposited into this mixture of lake water, they might live ten days, or they might live twelve days. In fact the number of days that they might live has not and cannot be accurately determined?

A. According to experiments, the typhoid bacilli disappear in lake water in six to eighteen days, according to the temperature.

Q. Now then, taking into consideration the fact that you testified to a few days ago, that reasoning by bacteriological analyses, the germs of typhoid would live longer in the running water than they will in the laboratory experiments, taking those things into consideration, might not those germs live not only five days, but ten, twelve, fifteen or twenty days additional in the Illinois river water, mixing with the water from Lake Michigan?

A. They might live somewhat longer.

Q. In other words, there is nothing in the science of bacteriology that can be made perfectly applicable so as to be reasonably safe at all times, and to express an opinion that would carry with it a degree of certainty and a degree of accuracy, is there, as to the exact longevity of the typhoid

7798 germ in a running stream?

A. Yes, I think a bacteriological examination allows of some opinions in that matter to be expressed.

Q. And under the conditions that have been assumed, the typhoid bacillus might live five, it might live ten, it might live fifteen, it might live twenty or even thirty days more, by the analyses that have been made by various bacteriologists in this country and Europe, isn't that true?

A. That would depend entirely upon how pure the water is and what the temperature of the water is.

Q. Isn't it true that it might do that, taking all these assumptions as true, and these experiments that have been obtained by bacteriologists in this country and in Europe?

A. A typhoid bacillus can live, as stated before, eighteen days in Lake Michigan water, according to the greater or lesser presence of organic life and saprophytes.

Q. But professor, going back now to all the assumptions with reference to the typhoid germ being deposited in the sewers of Chicago and remaining there one day; going back to the assumption that it has been known to live five days in sewage, and going back to the assumptions contained in the preceding question with reference to the longevity of the germ in running water as compared to the longevity of the germ in the laboratory 7799 experiment, are not the conditions so uncertain, and is not the field in such an unexplorable condition, taking into consideration the fact that the bacteriologists have found that they live in samples of water taken from running streams, from five to thirty days, that they may pass from the sewers of Chicago into the canal, into the Illinois river, into the Mississippi river and pass to the chain of rocks in less than thirteen or fourteen days, isn't that a fact?

A. No sir, that is not a fact in my opinion.

Q. But taking these assumptions that I have stated as true, isn't that a fact?

A. Yes, but they cannot be accepted, for this reason: We have a continual pollution of the river from Chicago to St. Louis, a river which receives pollution at all times of all forms of material, of organic material and saprophytes, therefore even if living typhoid bacilli should pass the Bear Trap dam, and even if they should get much farther down, they will be constantly exposed again to overgrowth by the saprophytic bacteria and will be constantly exposed to the destructive effects of such overgrowth. Further, the temperature of the water is too low to allow multiplication.

Q. Then professor, if that be true, what effect would the additional discharge of 250,000 cubic feet per minute of water into the Illinois river by means of the drainage canal, 7800 have upon carrying the germs farther down and into the Mississippi river?

A. It would affect and increase the dilution.

Q. Wouldn't it have the effect of hastening their journey on into the Mississippi river before that?

A. Yes, but it would also have the effect of greater dilution and greater separation of the individual germs.

Q. We are not talking about the dilution now; we are talking about the ability of the typhoid germ to live in the canal water and be carried in that water. Now then I want to go back to the original assumption and I want that read, and I want the witness to answer, confining himself to the assumption and taking it for granted that the assumption stated in the question is true.

(Question repeated).

JUDGE SPRINGER: I object to it because the assumption does not state all the conditions which exist in the waters of the drainage canal, the Desplaines or the Illinois rivers, which would materially affect the longevity of the typhoid germs in such water.

A. You pre-suppose a number of conditions which I have convinced myself are impossible, so what is the value of an opinion on such a hypothesis?

7801 Q. It may be of great value to me, and I admit that you do not accede to all those assumptions, but assuming or taking it for granted that all those assumptions are true, what would you say?

A. The most serious one of the assumptions in your question is that bacteriologists have found in river waters typhoid bacilli for thirty days. Now that is not so.

Q. Well I have raised it from five to thirty days.

A. But they have not found it in river water.

Q. They have been found in the laboratory, from the river water?

A. For thirty days?

Q. Yes.

(No answer).

Q. (Question repeated).

A. If all those assumptions were true, of course.

Q. It would?

A. Yes sir.

Q. Now then professor, under the same assumption, with the addition, that all sorts of pollution are removed from the Illinois river and the Illinois river valley, so that the Illinois river valley would be in its primal condition, state whether or not these germs would not reach the Mississippi river and the chain of rocks, if discharged into the Illinois river
7802 through the drainage canal?

JUDGE SPRINGER: I object to this question; that these assumptions are utterly impossible and that any answer based upon such assumptions would be immaterial, irrelevant and would not tend to prove any of the issues involved in this case.

A. That is practically what I would have said, that there is no such thing as a river like the Illinois river which can possibly be pure; that even if no sewage, from adjoining cities along its course would be turned into it, it would still be polluted with various micro-organisms, and more so after heavy rains and floods.

Q. Professor, assuming that all sorts of pollution from the sewage of cities situated upon the Illinois river water-shed, and pollution from domestic animals were eliminated, so that the Illinois river and the watershed of that river would be in its primal condition; state whether or not, in your opinion, the germs of typhoid fever and other pathogenic germs would not pass from the sewers of Chicago into the drainage canal, the Desplaines river, down the Illinois to the Mississippi; assuming that they would not perish in the sewers or in the drainage canal within two days, within the two days that they are confined therein, if so confined, and assuming further that it requires less than fifteen days for the water to flow from Lake Michigan to St. Louis by means of the drainage canal, the
7803 Desplaines and the Illinois rivers?

A. If all those impossible assumptions were true, the typhoid bacillus would no doubt arrive there.

Q. And be virulent?

A. That is another question, whether it would not have lost its virulence; it might and it might not.

Q. What is your judgment about it if it had lived fifteen days, would you consider it virulent, as a bacteriologist?

A. With nothing else to affect it, except the low temperature, during the fifteen days, if it had been virulent before, it probably would preserve its virulence.

Q. Professor, assume that the number of typhoid germs discharged by a sewer is millions and millions per day; that the time of flow from Chicago to St. Louis is ten days; that 99 per cent of the original number of bacteria die in ten days, then it would be a fact wouldn't it, that the number of typhoid germs coming from Chicago, passing the chain of rocks at St. Louis would average ten thousands of millions daily, isn't that true?

JUDGE SPRINGER: I object to the question upon the ground that the assumptions have not been established and cannot be proven in this case.

A. These are again purely assumptions and entirely opposed to the true conditions existing, both in the sewers
7804 or in the drainage canal, but if these assumptions were true of course those calculations would no doubt be correct.

Q. Now then, professor, under these assumptions or conditions, if ten thousand millions of typhoid germs pass the chain of rocks daily, coming from Chicago, is it not reasonable to expect that a large quantity of them should enter the St. Louis intake and a great many of them be swallowed by the people of St. Louis find their way into the milk, bread, vegetables, and at room temperature produce a media causing the multiplication of the typhoid bacilli, that would infect the families, and would affect the health and endanger the lives of families in St. Louis?

JUDGE SPRINGER: I object to this question because it assumes a statement of facts which have not been proven in this case, for the reason that those samples of water taken in St. Louis at the chain of rocks, in the Missouri river at its mouth, in the Illinois river at Grafton and the Illinois river at various places between Chicago and Grafton, and also in the Illinois and Michigan canal and in the drainage canal and in Lake Michigan, there has never been a typhoid bacillus found come from Chicago and passed to the St. Louis intake is without any foundation in fact and cannot be assumed as a 7805 fact that is based upon anything in this case.

MR. JEFFRIES: In answer to the objection of counsel for defendant, I suggest that the witness has stated that on the examination of water known to be infected with typhoid germs, bacteriologists have been unable to obtain a germ in that water. I will also suggest to counsel, that in the event of one typhoid germ being discovered in the samples of water that were taken by both parties in this controversy from the Illinois river or the Mississippi river below Grafton, taking into consideration the very small amount of water examined, and that had the river been infected with typhoid germs, proportionately throughout the entire volume that it would have meant death and destruction to all the people using that water for drinking and domestic purposes?

A. Even if all those assumptions were true, the possibility of millions of typhoid bacilli coming from Chicago to the chain of rocks would be absolutely impossible, even if all the typhoid bacilli of all the typhoid cases in Chicago would reach without destruction the chain of rocks, the dilution would be such a tremendous one that but very few of them could enter the inlet.

Q. Professor, if that be true, why is it, that occasional 7806 discharges, and carrying out of the sewage from the Chicago river into Lake Michigan at the mouth of the Four Mile crib produce typhoid fever in Chicago?

A. Because the one bacillus that might have been in a million barrels of water happened to get into the milk supply of a number of families and produce by multiplication in a favorable temperature millions of bacilli and these people were drinking cultures of them. Such a multiplication does not take place in water.

Q. And might not that condition also exist at the other end, to-wit the chain of rocks?

A. Yes, but you referred to the direct infection by water, and the numbers of typhoid bacilli which would arrive in that way from Chicago.

Q. Professor, do you mean to say that, assuming that there are ten thousands of millions of typhoid bacteria daily passing down the Mississippi river at the chain of rocks, that necessarily a large quantity of them will not be taken into the water system of St. Louis at the chain of rocks?

A. Owing to the tremendous dilution.

Q. In other words, that if all of the typhoid bacteria that are discharged by the people of Chicago, were deposited into the Mississippi river one mile above the chain of rocks, that the dilution would be so great that it would not affect
7807 the health of the people of St. Louis, do you mean that? Then if you do, professor why is it that the people are called upon to build filtration plants, and why is it they are called upon to expend large sums of money to purify the sewage of the larger cities of this country and of Europe?

A. Because a polluted river constitutes a nuisance, and because in such infectious material, if deposited right at the intake in immense quantities, the conditions are entirely different than they are in this case where 300 miles away a septic tank receives all the sewage of a city and destroys it.

Q. I understood,—I insist professor, that you did not answer my question. You stated in answer to a question a few moments ago that you believed that if all the typhoid fever germs discharged by the people of Chicago or by the typhoid patients of Chicago should pass down the Illinois river and arrive at the chain of rocks alive and virulent, that with the dilution there, they would have no effect upon the life and health of the people of St. Louis?

JUDGE SPRINGER: I object to the question and submit that he didn't say that.

MR. JEFFRIES: I submit that he said those very words.

A. All the typhoid bacilli that are produced by all the
7808 typhoid cases in Chicago, if they were all turned into the river and if they were not exposed to any conditions whatever of destruction and if they all arrived in the Mississippi at that locality, they would be so far distributed and so diluted through the immense amount of water, that the number of them would be inappreciable, and that it would be a great question whether any of them, even one, would enter the inlet at the chain of rocks.

Q. Professor, do you know or have you any information upon the volume of water that flows past the chain of rocks in the Mississippi?

A. I have only my own inspection which was made recently of the drainage canal, the Desplaines, the Illinois river, and the Mississippi and the Missouri.

Q. Do you know whether or not professor, that for months the volume of flow past the chain of rocks in the Mississippi is less than 600,000 cubic feet per minute?

A. No, I don't know that.

Q. Don't you know professor, that the volume of flow down the Mississippi river past the chain of rocks during the greater part of the summer season and the early fall season is less than 400,000 cubic feet per minute; in other words is not double the amount of water that passes through the drainage canal at Chicago. Not knowing this, I will ask you professor, if it
7809 would not be important and necessary for you to know
the exact volume of water which would flow down the Mississippi river past the chain of rocks, in order to determine whether or not there would be a sufficient dilution to protect and be a constant barrier against any deleterious effect upon the health of the people of St. Louis, on account of taking in the typhoid germs that might pass there?

A. I will repeat here in answer to that; if there is sufficient river water to be fifteen times that of the sewage, and the flow per second is one and a half meters, that no sedimentation banks of sewage form in the river, that no putrefaction or stench forms, that no algae or fishes are destroyed, that the chemical impurities are insufficient and that the bacterial impurities disappear in the purification zone. This I have stated before, and it really represents the opinion which I have formed, with regard to the sanitary side, although I have not attached much importance to this statement before, but you seem to insist on having me answer such questions, and therefore I have simply stated here the opinion of authorities on sanitation.

Q. I would not have insisted upon such answers professor, unless you had qualified and so testified in your direct-examination.

7810 A. Not in the direct; that was in the cross-examination.

Q. I want to know professor, if upon your proposition and your statement that you do not believe that if all the typhoid fever germs coming from the typhoid patients of the city of Chicago were passed down the Illinois river, were to pass down the Illinois river into the Mississippi river and on past the chain of rocks and be alive and virulent, it would not depend largely upon the volume of water passing down the Mississippi past the chain of rocks in order to determine what effect, what material effect that would have upon the life of the people of St. Louis?

JUDGE SPRINGER: I wish to enter an objection to this question and to all questions of similar character for the reason that the assumptions are utterly impossible and that any answer based upon such assumptions would be immaterial, irrelevant and would not tend to establish any of the issues involved in this suit.

MR. JEFFRIES: I suggest there is not a single assumption in the question that was not injected into the controversy by the witness himself.

JUDGE SPRINGER: The witness has never suggested that thousands of millions of bacteria could come from 7811 Chicago and get to St. Louis.

MR. JEFFRIES: The witness has suggested that if he believed that all the typhoid bacteria from the typhoid infected persons of Chicago were discharged into the canal and passed down the Illinois river to the chain of rocks and arrived there active, virulent and alive, it would have no effect upon the health or life of the people of St. Louis.

JUDGE SPRINGER: Even if he did state that, it would be utterly immaterial, because it is based upon an assumption of facts that do not exist and cannot exist, and therefore any answer upon this subject is utterly immaterial and proves no issue in this case, nor tends to prove any.

MR. JEFFRIES: Then I take it for granted that counsel admits the position that inasmuch as it is not material how much bacteria reach the intake tower at St. Louis, that the proof of their deposition in Chicago and presence, and ability to be present in the lower stretches of the Illinois river is all that is in controversy in this case.

JUDGE SPRINGER: No, the assumption is whether those typhoid germs will come from Chicago to St. Louis and is an assumption that is utterly impossible under any statement of the case. Nobody would ever assume that all those germs could possibly get to St. Louis.

7812 MR. JEFFRIES: But the witness has relied upon dilution, and this question is based upon the statement that he makes himself, and for that reason we have a right to propound the question.

THE WITNESS: I do not like to answer questions which are put on such purely theoretical assumptions and then afterwards be accused of having expressed opinions that are not in harmony with Mr. Jeffries' conviction. I do not wish to go on record as saying that if all the germs or bacteria of all the typhoid fever patients entering the river, if there was absolutely no destruction whatever by any saprophytic bacteria or products, could reach the chain of rocks, that none of those that should get there, got into the intake. I stated and want to be understood that the dilution would be such a tremendous one, that there would be very few only, and that those few would not produce infections by drinking that water containing them. This was the idea which I have expressed right along, of not believing in direct infections with water that contained greatly diluted typhoid discharges, so if you say that I have denied the possibility of any typhoid bacilli entering the inlet under the assumptions stated, I have either expressed myself wrongly, or you have misunderstood me.

Q. Well, the record will show what you said professor. Is it not necessary to know in this connection and in the con- 7813 nection about which we have just been speaking, the volume of water that passes down the chain of rocks at all times, in order to determine whether or not the sewage and typhoid germs from Chicago would have any deleterious effect and would sufficiently dilute the water as to render its sanitary condition safe, in the event that it can be rendered safe if typhoid germs had been deposited into it.

JUDGE SPRINGER: I object to the question upon the ground that one of the assumptions is that the typhoid fever germs from Chicago reach the St. Louis intake, an assumption which has not been established in this case; but on the contrary it has been proven that they cannot.

A. My former answer was based on the fact that I have inspected the waters of those rivers.

Q. MR. JEFFRIES: At all times of the year?

A. No sir.

Q. The question is professor, is it not necessary to take into consideration the volume of water passing a given point?

A. Certainly, but what will become of billions of minute organisms like these in a body of water like that of these three great rivers. It would be a similar dilution to that of gallons
and gallons of arsenic solution being poured into the
7814 Illinois river, and then employing the finest chemical
tests for arsenic on the St. Louis water supply. Not the minutest trace of arsenic could be found anywhere.

Q. If that is true, why is it, that typhoid fever has been traced by scientists and by competent men to Lake Michigan, or rather to the city of Chicago from Lake Michigan, to the city of Cleveland, Ohio, from Lake Erie, and would not the dilution in the lakes be far greater than the dilution in the Mississippi river or in any river where it is confined by narrow banks?

A. The conditions were, no doubt, due to sudden flooding of sewage into the lake and intakes by winds and storms.

Q. And the sudden floodings which you speak of, into the lake in part resemble the current of the river as it flows down the stream, and in addition to that the conditions in the river are not such as to allow sedimentation to take place to the same extent it does in the lakes, isn't that true?

A. During a storm, if sudden pollution of the lake takes place by sewage material containing typhoid bacilli, there would not be any chance for sedimentation either.

Q. And there never would be any chance for sedimentation in a river as long as the stream was flowing?

7815 A. Not in the river.

ADJOURNED until 10:00 A. M. following morning, Thursday, October 8th, 1903.

7816 10:00 A. M., Thursday, October 8th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. F. ROBERT ZEIT,

resumed the stand for further cross-examination by Mr. Jeffries, and testified as follows:

Q. Professor, we were speaking at the close yesterday, about dilution. I want to ask you that if you should deposit three or four virulent typhoid germs into a cubic foot of water, knowing that those germs were in that water, would you recommend that water for domestic use in the household?

A. I would not.

Q. If any city obtains a water supply that is infected with typhoid germs to any such extent, you would not consider that water good and safe for domestic purposes, would you?

A. That has not been claimed in my testimony.

Q. But professor, assuming now that they are there in those quantities, three or four to the cubic foot of water?

MR. DRENNAN: That is objected to as being so foreign to any of the facts in this case as to become purely imaginary.

7817 MR. JEFFRIES: I suggest that it bears upon the credibility to be placed upon this witness' testimony yesterday afternoon on the question of dilution.

A. It should not be recommended on the ground that even if it did not produce any direct infections by the drinking of the water itself, it might pollute articles of food and then allow rapid multiplication of typhoid bacilli at room temperature, leading to indirect infections.

Q. It might get in the other cultures?

A. Other media such as food, milk, etc., and multiply there under favorable temperature conditions and in that way produce indirect infections if the water itself had not been exposed to those conditions of saprophytic overgrowth, which lead to the destruction of pathogenic germs.

Q. But professor, wouldn't there be great danger of producing this growth upon vegetables and various media in the house or in the room where the family live, if the water was taken into that room containing these germs?

A. If the water contained living typhoid bacilli, yes.

Q. Now, that I understand is your theory of the matter. In other words, that the infection comes on account of the growth of the germ upon some media in the room rather than upon taking the typhoid directly into the human system by drinking the water?

A. Now Mr. Jeffries, you have continually called that a
theory of mine. It is not. This is the accepted opinion
7818 of the majority of sanitarians the world over.

Q. Well, whether it be your theory or not, professor, that is your opinion as drawn from your experience as a bacteriologist?

A. And from reading of the experiences of the sanitarians the world over, and my opinion is based upon the same argument they base theirs. The biology of the typhoid bacillus is such that direct water infections can almost be excluded. In fact some say, can entirely be excluded because the organism does not multiply in water at the usual temperature of drinking water, bacteria and saprophytic bacteria which multiply well at these low temperatures. Under those conditions a typhoid bacillus cannot multiply even if it remains alive. It cannot multiply unless temperature and culture media are favorable. This is not my individual and personal theory, but is the opinion of sanitarians in general,—with some exceptions.

Q. Then professor, there would be as much liability of contracting typhoid fever if the water containing those germs were used in the household at room temperature, and used to
wash vegetables at the proper temperature, and in various
7819 ways at proper temperature, as there would be if they
should drink the water,—conceding that they could contract it by drinking?

A. They, in my opinion, could not contract it by drinking the water because the number of the typhoid bacilli would be too small, due to dilution.

Q. Now this is the question professor: Assuming now that there are two ways, one by drinking the water direct, and the other by indirect infection, which you say is the accepted way. Now then, assuming that it may be contracted in both ways, we will take it for granted that science is divided on that proposition; take it for granted that it can be contracted in both ways, are they not as liable to contract it by reason of its being brought into the household and used in cleaning vegetables at the proper temperature, and in various media at the proper temperature in the household, as they would be in drinking it direct?

A. There are some exceptional conditions in which a direct infection could, no doubt, take place. If the sewage or the excrements of a typhoid, fever patient, containing innumerable numbers of typhoid bacilli should enter a well in 7820 large quantities, and such highly and recently polluted water be consumed, it might be possible that the necessary numbers to infect would be present. Such conditions would not exist in rivers where great dilution takes place, or in lakes where dilution reaches a tremendous figure. The infections by lake and river waters must always be indirect and not direct.

Q. Then professor, your position is that infection can be more readily brought about by smaller quantities of bacteria in the water when used in the household for domestic purposes than in the case of larger quantities taken into the human system directly by way of drinking the water?

A. Yes, because small numbers of typhoid bacilli contained in the river or lake water could, on favorable culture media, when kept at favorable temperatures, multiply rapidly and produce millions of bacilli. Such infected food would contain millions more of bacilli to the cubic centimeter than well water which had received the discharges of a typhoid patient.

Q. Now then professor, assuming that typhoid fever germs live from ten to twenty days in the sewage of Chicago, the Chicago river, the drainage canal, the Illinois and the Mississippi rivers, as they flow from the sewers from Chicago to and down the Mississippi river; assume that they are dis- 7821 charged into the Illinois river from the Desplaines river, and assume that the Illinois river is frozen over with ice from mouth to source, that the Mississippi river in turn is frozen over from Grafton to the point below the chain of rocks. Assume that the water coming from Lake Michigan and the drainage canal passes the chain of rocks within from ten to thirteen days, would not disease producing germs in larger quantities find their way to the Mississippi river at the chain of rocks, than they would in the summer time when the river is open?

A. The lower the temperature the longer the life of pathogenic bacteria, because the saprophytes do not overgrow them. That is true as a general proposition. Even pathogenic bacteria will eventually decrease in number by very low temperatures to which they have been exposed for a long time. The low temperature not only prevents the growth of parasites but also of saprophytes, and therefore they will multiply less and the typhoid bacillus—

Q. But parasites never grow in a running stream do they?

A. If the temperature of water should rise to that of blood, or even less, and there would be no increase of water bacteria or saprophytic bacteria, there might be even a little multiplication, but as a—

Q. But as a general proposition?

A. But as a general proposition they do not, because 7822 water bacteria and saprophytes are more favored by the usual temperature of water and thus overgrow disease producing germs. This overgrowth is the important element in the destruction of pathogenic germs.

Q. But under the conditions assumed in the question, what would be the effect at St. Louis as compared to the conditions which would naturally exist in the summer time?

A. The destruction of organic material by multiplication of saprophytes would be slower and the typhoid bacilli, or some other pathogenic bacteria might live longer. Some disease germs would be destroyed by low temperature; for instance the cholera vibrio dies in ice in a few days.

Q. How about the typhoid germ?

A. The typhoid germ would live longer. Some disease producing bacteria are more susceptible to low temperatures than others. The typhoid bacillus lives much longer at low temperatures than the cholera vibrio.

Q. Now professor, assuming that typhoid fever germs pass from the canal into the Illinois river, and that as they reach the Illinois river they meet a flood, what effect would that flood have,—a flood in the Illinois river, have upon carrying them down stream?

A. The flood would mean greater dilution; it would sep-
7823 arate them further apart. It would mean more water;
it would mean more rapid flow, so they would pass a further distance down the river than if the flow was slower as in low water. The saprophytic life and destructive effect of organic matter would be less.

Q. In other words there would be greater quantities of typhoid fever carried down the river by the flood alive?

A. Greater numbers of typhoid bacilli could pass further down the river before they were destroyed, yes sir.

Q. And if they live from ten to thirteen days, and the water of that flood reached St. Louis within the thirteen days, they might flow on right through, might they not?

A. If they could live thirteen days, which is improbable, because floods carry immense quantities of organic material into the river and immense numbers of other bacteria, which would again take up this competitive struggle. The more the flood the more impurities would reach the river and the more saprophytic bacteria would be present, and therefore the struggle would be the same. The only difference that I can see is the greater dilution of pathogenic germs and the more rapid flow, so that less time is given for these competitive struggles to take place.

Q. And therefore larger quantities would reach the river at St. Louis?

A. If that was possible.

7824 Q. If they got into the flood?

A. If they were not destroyed by all these elements mentioned, in thirteen days, of course they would still be there.

Q. Professor, what is it that destroys the typhoid germs? In other words, is it an absolute warfare between the saprophytes and the parasites or is it simply because of the overgrowth of the one that the other disappears?

A. The factors are the following:

First, the overgrowth of saprophytes.

Second, the excreted material present in the water of these saprophytes. The more organic material present, the more rapidly do these saprophytes multiply and the more of these excretion products.

Third, the temperature. The more favorable the temperature for the growth of saprophytic life, the more rapid the destruction of the typhoid bacilli. I might now add another factor which I have never mentioned, and that is the factor of sunlight, or light—

JUDGE SPRINGER: What effect would that have?

A. The destructive effect of sun light upon all disease producing bacteria in rivers and in lakes. Aside from the competition between saprophytic and pathogenic bacteria, there are some other factors.

7825 Q. But the fact is that these germs have been found to live in the sunlight for days and weeks?

A. No sir, pathogenic bacteria die in sunlight in a few hours.

Q. No, but I mean in the samples of water in which you undertook to imitate the conditions in the river as far as possible?

A. In my experiments I excluded the effects of sunlight entirely. I think my experiments were rather more favorable to the life of the typhoid bacillus, than natural conditions in the river.

Q. Well don't you know that experiments have been made by competent bacteriologists in undertaking to imitate as far as possible the conditions with reference to light in the river?

A. Experiments upon the longevity of the typhoid bacillus with regard to diffuse light?

Q. Yes?

A. Why I have done that too. In my series of experiments I exposed some of the flasks and tubes in the dark room to different temperatures, and another series in diffuse daylight. In diffuse daylight typhoid bacilli disappeared quicker than they did in the dark.

Q. Now then, professor, in time of flood the water is very turbid, is it not?

7826 A. Yes.

Q. And that has a tendency to prolong the life of the germ?

A. By decreasing the effect of light.

Q. Professor, you have spoken of the zone of bacterial purification in streams below cities,—have not bacteriologists described a zone of pollution of streams above cities?

A. Above cities—

Q. Some bacteriologists, I don't mean all.

A. I think sanitarians have had most to do with that, and it wasn't so much an examination of the bacteria in the streams above the city which led them to speak of such pollution as it was the general knowledge that the discharges of diseased persons and sewage had been known to have been poured into the river, above cities.

Q. Assuming that typhoid fever germs will live in the Chicago sewers, the drainage canal and the Illinois river for thirteen days or longer, and assuming that the germs from the sewers of Chicago when discharged into Lake Michigan sometimes find their way to the Four Mile crib, and after reaching the crib cause typhoid fever in Chicago among the users of the water from that crib; assuming further that the typhoid germs discharged into the drainage canal entered the water suply of St. Louis within thirteen days; assuming further that the dilution of said germs in the water of the Mississippi river
7827 at the chain of rocks is not greater than that of the
typhoid germs in the water of Lake Michigan at the mouth of the Four Mile crib, would not the using of the water from the Mississippi river at the chain of rocks by the people of St. Louis produce as much typhoid fever as would be produced among the people of Chicago using the water of Lake Michigan drawn from the Four Mile crib?

A. The two conditions in my opinion, cannot be compared because even if it could be proven that direct infections by swallowing the water did occur or that indirect infection occurred in the manner indicated, by typhoid bacilli multiplying in milk and other food at favorable temperatures, from water supplied by the Four Mile crib, a severe storm on Lake Michigan might rapidly carry out large masses of pollution to an intake, located only four miles from shore, whereas the distance from here to St. Louis is over 300 miles by way of the river, and there would be a great deal more time for destruction of pathogenic bacteria that had entered it, than if fresh sewage containing typhoid bacilli, just received by the lake, were suddenly washed out by storms and flooded into the intake.

Q. Professor, answer the question.

A. Well, there are those differences between the two conditions.

7828 MR. JEFFRIES: Read the question.

(Question read.)

JUDGE SPRINGER: I suggest that the witness has already answered this question.

MR. JEFFRIES: I suggest that the witness has not answered a single word of this question.

JUDGE SPRINGER: For the reason that the conditions are not comparable in this, that the assumption is that the typhoid germs from the sewers of Chicago reach the intake within thirteen days. They may have reached it within one day, but in the other case they must have a much longer time to reach their destination, and the conditions would all be changed.

MR. JEFFRIES: Now answer the question professor.

A. I think I have answered it before.

JUDGE SPRINGER: I insist that the assumption which states that the germs that enter the St. Louis intake had been deposited in the Chicago sewers for more than thirteen days before they reached the intake, in order to make the comparison whole in the one case they may have reached the intake in one day and in the other case it is impossible to reach it until after ten or twelve or fifteen days, or thirteen days, whatever you fixed it.

Q. MR. JEFFRIES: What do you say as to the question professor?

7829 A. How does the question stand now?

Q. The question stands just as it did before.

A. If typhoid bacilli from whatever source they come, entered the intake of St. Louis, they are capable to produce the same conditions in St. Louis that they would if typhoid bacilli reached the city of Chicago from the four mile crib. I mean by this that typhoid bacilli, from any source, entering the intake at the chain of rocks at St. Louis, will not produce a direct infection by the drinking of the water, because too small in by any person, and that assumption that millions of them have number—but they are capable of getting upon favorable culture media, such as milk and foods, multiply at room temperature and produce infections.

Q. So that it would be as liable to produce as much fever in one case as in the other?

A. Every one swallowing such cultures of typhoid bacilli on food stuffs, which result when a few germs in the water multiply under favorable temperatures, could be infected and develop typhoid fever.

Q. Now then professor, I will state the question in another way. Assuming that typhoid fever germs will live in the Chicago sewers, the drainage canal and the Illinois river for thirteen days or longer, and assuming that prior to the opening of the Chicago drainage canal typhoid germs lived in 7830 the Chicago river and Lake Michigan for thirteen days or longer, and that they sometimes found their way to the Four Mile crib and after reaching the crib caused typhoid fever in Chicago among the users of the water from that crib; assuming further that the typhoid germs discharged into the drainage canal since the opening of the canal, enter the water supply of St. Louis within thirteen days; assuming further that the dilution of said germs in the water of the Mississippi at the chain of rocks is not greater than that of the typhoid germs in the water of Lake Michigan at the mouth of the Four Mile crib, prior to the opening of the drainage canal, would not the use of water from the Mississippi river at the chain of rocks by the people of St. Louis produce as much typhoid fever as would be produced among the people of Chicago using the water of Lake Michigan drawn from the Four Mile crib?

A. That is true, but the whole proposition has been proven to be impossible.

Q. Professor, this is an assumption which I am responsible for. I am responsible for the question; you are responsible for the answer, and I want you to answer the question?

A. I do.

Q. Well, now let us hear your answer.

7831 A. I said, "Yes." But the proposition itself is excluded by my testimony which states that they do not live thirteen days under the conditions stated, in the drainage canal and in the Illinois river.

Q. But assuming these conditions to be true, as contained in this question, you will have to admit that they would produce as much typhoid fever in the one place as in the other, would you not?

A. I answered that with "Yes," before.

ADJOURNED until 1:30 p. m., same day, October 8, 1903.

7832 1:30 p. m., Thursday, October 8, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

By agreement between counsel, witness Prof. F. Robert Zeit was temporarily withdrawn from the stand.

FRANCES C. BLANCHARD,

called as a witness in behalf of the defendants, being first duly sworn, was examined in chief by Judge Springer, and testified as follows:

Q. State your name, residence and occupation, madam?

A. Frances C. Blanchard; Wheaton, Illinois; physician.

Q. State whether at any time you were employed by Professor Long, for the purpose of taking samples of water from the head waters of the DuPage river?

A. Yes sir, I was asked by Professor Long to send him samples in the fall of 1899.

MR. JEFFRIES: I object to any evidence as to samples of water being taken from the head waters of the DuPage or
any of the tributaries of the Illinois river for the reason
7833 that any analyses that may have been made of such wat-
ers, as applicable to the condition of the water in the Illinois river, is incompetent, irrelevant and immaterial, and for the reason that such evidence will throw no light upon the question as to whether or not the disease producing germs that flow from the sewage of Chicago by means of the drainage canal reach the waters of the Mississippi along the shore of the state of Missouri.

JUDGE SPRINGER: For the purpose of facilitating this examination, counsel for respondents agrees that this objection may be considered as having been made to all of the questions put to this witness, as they relate to one of the tributaries.

MR. JEFFRIES: And such further objections as I may see fit to make from time to time.

JUDGE SPRINGER: At what time did you begin to take the samples and when did you quit?

A. I began I think about the first of November or the last of October, I do not remember the dates.

Q. What instructions did you receive from Professor Long, if any, in regard to taking these samples?

A. There were printed instructions on the backs of the cards that were sent me and I referred to the cards.

Q. Did you follow those instructions?

7834 A. I did sir, most implicitly.

Q. What kind of bottles or receptacles did you receive for the purpose of containing this water?

A. If I remember correctly they were gallon bottles in cases.

Q. How were they prepared, if you know?

A. There was one small vial also. They were prepared, stoppered and covered by some rubber, I think.

Q. What did you do in reference to taking the samples; how did you proceed to get the water from the stream?

A. The directions on the back of the card gave the method of the procedure. I remember one thing was that the bottle was to be opened after it entered the water before the water was allowed to enter the bottle.

Q. Did you follow that instruction?

A. I did.

Q. And closed it after you had it below the surface?

A. Yes sir.

Q. What did you do with the bottle when you filled it?

A. It was immediately stoppered and recovered and taken at once to the express office.

Q. Was it packed in anything?

A. It was packed in a box.

7835 Q. Was it packed with ice?

A. No sir, it was so late in the year that ice was not necessary. The latest collection was December 7th.

Q. How many samples in all did you take?

A. I collected three.

Q. Please look at the papers that I hand you and state whether those were the papers containing the instructions and the blank for making out the returns in reference to the water taken?

A. That is my handwriting and my signature, all of them.

Q. Did you fill those blanks?

A. I filled them myself.

Q. Did you, or do you recognize the instructions on the back?

A. I do.

Q. And those are the instructions that you followed?

A. I did.

Q. Are the statements made upon each of these cards in your handwriting, correct statements of the facts stated upon these cards?

A. They are so far as I was able to make them. They are correct.

7836 Q. These that are here are correct?

A. Yes, I did everything as I was ordered to.

Q. On these cards I observe the following date, the date of collection on one is November 9, 1899; on the other is November 23, 1899; on the other December 1, 1899. Are those the dates upon which these collections were made?

A. I think they are.

Q. Is this your signature upon each of them?

A. Yes sir, that is my signature.

Q. Have you correctly noted the temperature of the air and water, in the samples?

A. Yes sir.

Q. And forwarded them by express as you have stated?

A. Yes sir.

JUDGE SPRINGER: We will put these in as part of defendants' Exhibit 1 to 17 for identification.

MR. JEFFRIES: It is agreed by counsel for complainant that the cards so shown this witness are the same as defendants' Exhibit No. 3.

7837 CROSS-EXAMINATION, by Mr. Jeffries.

Q. Did you collect the samples in one bottle each day or two bottles?

A. Only one bottle was sent me at a time.

Q. And that was a large bottle?

A. Yes sir.

Q. You made no collection of the small bottles?

A. There was a small bottle, I think, in the same package.

Q. A four ounce bottle?

A. I don't remember the size of it. Two bottles in one express package, and they were collected at the same time.

Q. They all went to Professor Long?

A. Yes sir.

Q. You only made three collections?

A. I only made three collections, yes sir.

MR. JEFFRIES: Now I move to strike out all the evidence of this witness, and also the testimony of Professor Long with reference to the chemical analyses of the DuPage river water at this point, for the reason that this evidence is incompetent, irrelevant and imaterial. Incompetent because it does not tend to prove any issue in this case, and has no bearing
upon the issues in this case, and for the reason that even
7838 though the condition of the water in the DuPage river or
any other tributary of the Illinois river, was in any way essential in the determination of any question in this case, that a sufficient number of samples was not taken to be comparable with the conditions applicable to the Illinois river and for the reason that flood times are not considered, and low water stages are not considered, and that even the samples that were taken, were not taken with reference to the condition of the tributaries in low water stages of the river, and have not been considered.

RE-DIRECT EXAMINATION, by Judge Springer.

Q. Will you state what was the stage of the river so far as you could observe at the time you took these samples?

MR. JEFFRIES: I object to the question as not proper re-direct.

JUDGE SPRINGER: It is competent on the ground of your objection.

THE WITNESS: The water was low.

Q. Was it lower than ordinary?

A. It was not as low as I have seen it, but it is what you call low water.

Q. How large is that stream?

7839 A. It is not a very large stream, perhaps at Warrenville, where I took the samples, from eighteen to fourteen feet, it widens and narrows.

Q. In width?

A. Yes sir.

Q. How deep?

A. Perhaps a foot and a half or two feet.

MR. JEFFRIES: Now I renew my motion to strike out this testimony for the reasons stated in the motion just made.

(Signature waived.)

7840 PROF. F. ROBERT ZEIT,

resumed the stand for re-direct examination by Judge Springer and testified as follows:

Q. Professor, in one of the questions submitted to you on cross-examination by Mr. Jeffries, it was assumed that English authors or bacteriologists were more thoroughly informed on questions of sanitation and hygiene and bacteriology than the scientists of other countries. To this intimation you suggested your non-concurrence on the ground that you thought the German writers were better informed upon this subject. Now will you state what position the Franklands, the authors of a book called Micro-organisms in water, a work which Dr. Ravold in his testimony stated was of the highest authority, have taken with reference to the zone of bacterial purification in rivers?

MR. JEFFRIES: I object to the question for the reason that no such assumption was contained in any question that I propounded to the witness; that I did not refer to hygiene, but I referred to river pollution, and river pollution alone, and that the question so propounded to this witness in redirect examination does not contain the assumptions contained in the question which was propounded by me in cross-examination.

7841 JUDGE SPRINGER: I will modify my question by quoting the words exactly used by Mr. Jeffries whether "there is any people on the face of the earth that have made more thorough investigations of this subject than the English people." That is the phrase to which I referred in my previous question, and to which I have confined my assumption as stated therein.

Now what position was taken by them in reference to the self-purification of the River Dee, to which you referred?

A. Frankland states in his text-book that the River Dee affords a most perfect example of the repeated pollution and the repeated restoration of a stream to a state of comparative purity—

MR. JEFFRIES: I object to the witness reading from Frankland's as he is now doing.

Q. JUDGE SPRINGER: Does that book state the position of leading German bacteriologists on this subject, if so, please state the facts.

MR. JEFFRIES: I object to the question for the reason that the book is no evidence. The question is the opinion of this witness, and not as to what any other person will say, and for the reason that we have not Mr. Frankland or any other person from whom the witness might quote, here personally, in order to cross-examine him on the subjects about which this witness is testifying.

7842 JUDGE SPRINGER: This testimony in my opinion is competent for the reason that counsel for complainant has intimated that this witness was not supported by the English authors and writers on this subject and that he has a right therefore to show that he is supported by their writings.

MR. JEFFRIES: I object to the question for the reason that if, as assumed by Judge Springer, that any such position should be taken by the complainant, that the witness has no right to read from a book in support of his proposition, but that he may from his own memory and own information derived from reading publications upon the subject, or from his experience as a scientist, state relatively his position with reference to the positions of other men engaged in the same scientific investigation.

JUDGE SPRINGER: I submit that the highest evidence is the exact text of the writer.

Q. Now will you state as to the other question?

MR. JEFFRIES: I submit that there has been no evidence that the text-book which he is reading from was written by any person or persons testifying in this case, and there is no evidence that that position has always been maintained or was not subsequently shifted and changed by the writer of the book and that proof of these facts can only be obtained in a 7843 competent way by the judgment and opinion of the person speaking from the witness stand, and the witness stand alone and not through the medium of books.

Q. JUDGE SPRINGER: You may answer the question.

A. The Franklands state in their book, "It will be seen from a careful study of the numerous investigations which have been made on the behavior of pathogenic organisms in water, what enormous differences exist in their capacity for living in this medium, that whereas, some varieties are destroyed in a few hours, some will live and flourish for many months. Moreover, it is obvious how greatly in some cases, the character of the water influences the vitality of the micro-organisms, a point which is especially brought out in Trenkmann's experiments with cholera bacillus, and it is of particular interest to note how in the case of unsterilized waters, the ordinary water bacteria are able to overwhelm and suppress those foreign pathogenic forms which have been introduced. Krause's experiments are particularly instructive in this respect, for they exhibit the multiplication which takes place in the ordinary water bacteria, and the simultaneous disappearance which ensues of the pathogenic organisms introduced."

Q. State whether Trenkmann and Krause, referred to 7844 there, are recognized authorities upon the subject of bacteriology and hygiene in Germany?

MR. JEFFRIES: I move to strike out the answer of the witness, and all that he has read into the record for the reasons stated in my objection to the question, and my objection to his reading what he did into the record, for the reason first that it is not shown what it was that he read and for the second reason that it is not responsive to the question.

Q. JUDGE SPRINGER: Will you please state the page and title of that book?

A. The title of the book is "Micro-organisms in water," by Percy Frankland and Mrs. Percy Frankland, page 94, page 101, and page 331.

Q. What position have German scientists and bacteriologists taken on this subject so far as you know?

A. They have taken the same position that I have stated in my testimony.

Q. Are there any other German authors whose works you are familiar with, that you could cite upon that subject?

A. Yes sir, I could cite Rubner, Prausnitz, Flugge.

Q. Who is Mr. Rubner to whom you have referred?

A. Rubner is professor of hygiene at the University of Berlin.

7845 MR. JEFFRIES: I move to strike out the answer because Professor Rubner is not on the stand and we have no opportunity of cross-examining him.

Q. In what estimation is he held by scientists of the world?

A. He is considered as one of the foremost sanitarians of Europe.

Q. Can you cite any statements in his works upon this subject which show that you are not standing alone in reference to the longevity of pathogenic germs in river water?

A. Yes sir.

Q. Will you please do so and state what volume you are consulting?

MR. JEFFRIES: I object to the witness testifying as to whether or not he stands with others or alone on the question of longevity of disease producing germs, for the reason we have not the opportunity to cross-examine the persons who are the authors of the books that he now proposes to read from, and for the further reason it has been disclosed by this witness who is a witness for the defendants, that it is absolutely beyond the science of bacteriology to determine the exact duration of the time that they will live under all circumstances, and under such changing circumstances and conditions of water and flood and temperature, so that no laboratory test that may be made 7846 by any scientist upon the subject, could be compared, and could be taken as the true test to be applied to any running stream, when the lives of millions of people are at stake.

JUDGE SPRINGER: I will state in reference to this objection that these matters were not referred to in the examination in chief and are only called out at this time by reason of the course pursued in the cross-examination, in assuming that this witness was propounding a doctrine which was contrary to the accepted opinions of others on this subject, and that he has a right therefore to show that he is not standing alone.

MR. JEFFRIES: Standing alone on what proposition?

JUDGE SPRINGER: In reference to the questions to which he has been testifying.

MR. JEFFRIES: I said that it has never been questioned upon the part of the complainant that this witness stands alone as to the longevity of the typhoid or any other disease producing bacillus in running water. In other words that it has never been determined by this witness and has never been determined by any other scientist, and that it is so uncertain that scientists have been unable to agree as to the exact length of time that disease producing germs will live in running streams, taking into consideration the various changes which take place from source to mouth—temperature, flood seasons, freezing 7847 seasons, ice seasons, dry weather seasons and all other conditions that pertain to the various rivers throughout the world, so that it is a matter that is absolutely out of the reach of any bacteriologist to determine from a laboratory examintaion, the character of the water, and the disappearance of all pathogenic germs in any running stream, and that when such conditions are true as have been shown by this witness, who is a witness for the State of Illinois and the Sanitary District of Chicago, that any effort to limit the life and fix the life of a typhoid or other disease producing germ in a running stream to a certain definite number of days, is inadmissible, irrelevant and incompetent, when the life and health of the people of an entire state are involved.

Q. JUDGE SPRINGER: Now proceed, professor. I will ask you what language that book is printed in?

A. This is printed in German, and is a text-book on hygiene by Rubner, published in the year 1900. In the first place, as to my standing alone with regard to the question that direct infections by water did not occur—

MR. JEFFRIES: I object to the answer so far, because it is not responsive to the question. The question went as to the longevity of the germ.

7848 THE WITNESS: Well that comes too.

JUDGE SPRINGER: And on this subject I stated, spoken of in his testimony.

A. First with regard to my position that the indirect infection is the common way of infection of typhoid, and not the direct infection by drinking of the water itself. There are many other ways of carrying the infection from the diseased person to the well, than that by direct drinking of polluted water. Rubner states: "It is peculiar that even now days, after we know the biology of the typhoid bacillus so well, people cannot separate themselves from the theory that direct infections take place by drinking of polluted water, although it is well known that the typhoid bacillus can be carried and is carried in so many other ways, which would explain the epidemics that arise."

In the same connection he states that "in water, particularly in cold water, the longevity of the typhoid bacillus is longer than that of the cholera vibrio—that is the vibrio of Asiatic cholera—but the typhoid bacillus cannot multiply and dies in about six days.

MR. JEFFRIES: Now Professor, I want to get the page and the section of the book from which you read.

7849 A. This is page 931 and page 930 of the edition of the year 1900—the sixth edition of the book. 1900.

JUDGE SPRINGER: Read the title of the book?

A. The title of the book is "Text-Book of Hygiene, by Max Rubner, Professor of Hygiene at the University of Berlin, and director of the Hygienic Institute of Berlin."

On page 325 he states, that at the present state of our knowledge it has a certain value to determine, in an experimental way, the relations which pathogenic bacteria have to water. Experiments in which the artificial inoculation of cholera, typhoid, anthrax and pus germs into water was practiced, show that not one of these organisms persists; all of them die in a shorter or longer time. The rapidity of their destruction depends upon (a) the richness or the poverty in organic material

In slightly polluted waters, the quantity of organic material is too small to cause the growth of pathogenic germs.

(b) Upon the temperature. In ice, cholera vibrio died in a few days. The other bacteria named are more resistant. Anthrax spores live a long time.

(c) The third condition—the competition with other water bacteria. In sterilized water, which of course never occurs in nature, all pathogenic bacteria live better. Anthrax spores, cholera vibrio and typhoid bacilli die in non-steriled tap-
7850 water in a few days, at the temperature of 10.5 centigrade.

(d) The fourth condition. The influence of light destroys bacteria.

Furthermore, according to the practical conditions, or stimulating practical conditions, Kalinski infected wells with anthrax spores and typhoid bacilli, as well as with the excrements of typhoid fever patients, and could not find these germs after one week. According to these results, it is certain that the bacteria mentioned have no ability of multiplying in drinking water, but may remain alive a few days. The germs have lost a great deal of their danger because they cannot multiply."

Q. Professor, if there were not zones of purification in rivers, and if pathogenic germs were not short-lived, as you have testified, what would be the condition of the rivers in the world in inhabited regions?

A. I think I stated once before, that if there was no such purification of rivers, such natural purification of rivers of the polluted material that constantly enters these, the human race would long ago have died out by the overgrowth of pathogenic bacteria.

Q. Is the tetanus bacillus a water bacterium?

7851 A. No, it is a bacillus found in earth. It is most commonly found in nearly all earth, practically everywhere, where there is garden earth.

Q. May not tetanus spores reach St. Louis from Kansas City and other points along the Missouri river in the State of Missouri?

MR. JEFFRIES: I object to the question because it is irrelevant, immaterial and incompetent, and for the reason that the condition of the Missouri river is not in question, and for the further reason that proof of such condition of the Missouri river is no justification for the discharge of such germs into the Illinois river by the city of Chicago or by the drainage district thereof, and for the further reason, if it is a fact that the Missouri river is polluted at points above by the sewage discharges therein, they being situated upon the natural watershed of said river, that said statements and such position assumed by counsel for defendants should be concluded as an admission that said disease producing germs are deposited into the canal by the city of Chicago and pass from there down the Illinois river and the Mississippi to the State of Missouri, and that upon such confession, judgment should go for the complainant.

(Last question read.)

7852 A. Yes sir, they may. In fact tetanus spores will get into rivers in large numbers, after every rainfall that washes dirt into a river.

Q. What, professor, takes place in the human system when typhoid bacilli are taken into the system in drinking water?

A. If the number of typhoid bacilli is small, in my opinion, as I have already stated, no infection takes place. If the number of bacilli is large, and they are virulent, and the resistant forces of the organisms are reduced, then infection takes place. If any of the factors are lacking, no infection takes place. Even when large numbers of virulent bacilli are swallowed the resistant forces might be so great as to overcome the infection. In fact, if any of those factors would be lacking, no infection would take place.

Q. What are the resistant forces in the human system that prevent the fatal effects of drinking water containing typhoid or other pathogenic bacilli? 7853

A. We cannot definitely state what those influences are, although in a general way we may say the resistant forces of the organism may be reduced by exposure, starvation, destruction of red blood corpuscles, loss of blood, destruction of hemoglobin, lesions, where tissues have been more or less destroyed, and many other factors. The term resistant force does not allow of an exact determination although we mean by it the ability of the healthy body fluids and cells to resist destructive agents.

Q. Which are impossible of correct determination.

A. Yes.

Q. Professor, have you ever made any bacterial examinations of ice for the purpose of ascertaining the longevity of pathogenic bacilli which have been frozen in such ice?

MR. JEFFRIES: Objected to as not proper re-direct examination.

JUDGE SPRINGER: It is proper for the reason that ice was not referred to at all in the direct examination.

A. I have not.

Q. Have any such examinations, so far as you know, been made in this country or in Europe, if so, with what result?

7854 MR. JEFFRIES: I object to the question for the reason that the witness is undertaking to give the experiments of others, without having any personal knowledge on the subject and without ever having made any examinations of his own, and therefore he is incompetent to testify upon that subject, not knowing the manner in which the examinations are made, and more particularly not knowing the manner in which the particular examination upon which the witness is called to testify, were made, and for the further reason that the persons who made the examinations are not upon the witness stand and we have no opportunity to cross-examine them and whatever the witness might say on the subject would be merely hearsay and therefore not competent.

Q. (Question repeated.)

A. According to what I know of the literature on the subject of the experiments of others, the cholera vibrio died in a few days, and according to experimental work done by Winslow, under Professor Sedgwick's direction, typhoid bacilli also are destroyed within three weeks in ice. Although not entirely destroyed numerically, a great destruction of them takes place, and only very few remain after 3 weeks. The experiments of Hill of the Boston City Board of Health established the fact that typhoid bacilli died very rapidly in ice.

7855 Q. Assuming that ice should form in the Chicago drainage canal and the Desplaines and the Illinois rivers, should be frozen over as far down the streams as Peoria, and should continue frozen from six to eight weeks, and that the ice should then be broken up and float down the rivers, being obstructed as is usually the case, in its flow, by ice gorges and the dams in the river, and assuming that typhoid bacilli should have been frozen in the ice formed in the drainage canal and that they should be carried in that ice as far as the mouth of the Missouri river, and that the ice should melt before reaching the St. Louis intake at the chain of rocks; what is your opinion, based upon the experiments made by you to which you have testified in this case, and upon your general knowledge as a bacteriologist, would any of the typhoid bacilli thus borne from the drainage canal, reach the St. Louis intake alive, and would such bacilli be a menace or danger to the persons who might use the waters at that place for drinking or domestic purposes?

MR. JEFFRIES: I object to the question first, because the witness has not testified as to any actual experiments made by him with reference to the duration of the life of the typhoid bacillus in frozen ice. I object to the question for the further reason that it is unfair to the witness and to the complainant because it does not assume that the time consumed in carrying the ice from the Desplaines river and the Chicago drainage canal, to St. Louis, and I object to the question for the further reason that it assumes that the ice is frozen on the river, and remains so frozen for six to eigth weeks, for the reason that that ice is continually freezing from day to day, especially in cold weather time, and that as it freezes, bacteria being present they will be frozen in the ice, and for the further reason that there is no evidence that the ice would be retarded in its progress down the Illinois river after being broken up in the spring time, but on account of the floods and high water, it rushes directly from the place of breaking up to the Mississippi river. 7856

A. I will say in answer to that that there are two factors which would allow me to express the opinion that no living typhoid bacilli would enter the chain of rocks. The first one, the experiments stated with regard to the destruction of the typhoid bacillus at freezing temperatures, if the typhoid

bacillus should really be in the ice. The second one, the fact that if typhoid bacilli should really get into the drainage canal by way of the sewage from typhoid fever cases, that they might, by reason of their own motility seek the warmer strata of
7857 the water and not rise to the surface where the colder strata of water could be frozen.

Q. Then it is your opinion that they would not reach there alive under those conditions?

A. They would not reach there alive in either case. In the warmer strata saprophytic products would destroy them.

Q. Assuming the same facts to exist as those stated in the previous question, except that the bacteria contained in the ice were cholera, streptococcus and staphylococcus, would in your opinion such bacilli survive and be alive or a menace or danger to the people who might use the water at the St. Louis intake, for drinking or domestic purposes?

MR. JEFFRIES: I object to the question for the same reasons stated in the previous objection and for the further reason that the witness has not qualified as a sanitarian and has had no experience and no observations upon that subject and as to whether there would be a sufficient number as to what is a sufficient number of disease producing germs in water to constitute a menace to people using it and drinking it, this witness has not qualified himself as being able to give or express an opinion in reference thereto, having had no experience either in the science of epidemiology or in investigating the sanitary condition of water as applicable to the various large cities throughout the United States.

(Question repeated.)

7858 A. Cholera vibrio would die in a few days in ice. The others would probably disappear, if we can reason by analogy at least as rapidly as the typhoid bacillus, although I do not recollect from the literature, any experiments with ice as to the streptococcus, and staphylococcus. I can only reason by analogy here, but as regards a cholera vibrio, that is different; that has been determined. Cholera vibrio die in ice in a few days.

Q. Assuming the same facts to exist as these stated in the previous questions, except that the ice contained anthrax spores, in your opinion would such spores be dangerous to cattle that might drink the waters from the Mississippi river from the mouth of the Illinois river to the southern border of the State of Missouri?

A. Is this in reference to ice, or with reference to anthrax spores in general?

Q. With reference to the anthrax spores being in ice—the same conditions, except that the ice contained anthrax spores—would such spores be dangerous to the cattle that might drink the waters in the Mississippi river from the mouth of the Illinois river to the southern border?

MR. JEFFRIES: In other words, do I understand you to ask the witness whether or not the anthrax spores will
7859 live in ice, on their journey from Chicago to the Missouri shore of the Mississippi river.

JUDGE SPRINGER: No, I didn't ask him that. I asked him whether the anthrax spores thus borne would be a menace to cattle that might drink that water.

A. Borne by the ice, or borne without the ice, simply passing down?

Q. This would include of course the melting of the ice before they get there.

A. Well I can answer that in a general way. Anthrax spores remain alive under the most unfavorable conditions, therefore with anthrax spores we would simply have the question of dilution and separation in the water, and there would still be spores present. Now as to the infectious nature of anthrax spores we can only again take the actual experience of anthrax infections in general, and the fact that whenever an epidemic of anthrax amongst cattle or sheep has broken out, that it was confined to the immediate neighborhood of such source of infection, and that even where we know that the infectious material containing anthrax spores did get into the river, the cattle and sheep some distance down the river did not develop the disease, only those in the immediate vicinity of the original source of pollution being infected. Anthrax spores can
7860 live a long time in water, and we must, therefore, conclude that either the factor of great numbers of infecting bacteria is absent further down the river, due to great dilution, or

to the factor of lost virulence of the germ. Where intestinal anthrax amongst animals could be traced to direct pollution of rivers, the disease was only prevalent near the original source of pollution, and not further down the river. Man is not very susceptible to anthrax. We have had infections, but they have been very rare and could not be traced to the drinking of infected water.

Q. Has there been any case of anthrax infection to your knowledge recently?

A. I know of one river which was polluted with the discharges of a tannery where sole leather was produced, the hides having come from Brazil and China. In that particular
7861 instance the cattle which were grazing on the meadows
just below the tannery died of intestinal anthrax or anthrax bacteraemia, having great numbers of anthrax bacilli in the blood. They had swallowed food or water of the polluted river containing anthrax spores. Further down on this river, however, no death of cattle took place. It was all within the immediate vicinity of this tannery, through an area of probably at the most one mile. The river overflowed both banks in the spring and overflowed the banks further down the river just as much as in the immediate vicinity of the tannery, and yet the cattle further down the river appeared to be perfectly safe from infection. Now, we cannot for a moment think that there should not have been anthrax spores for long distances along this river. I refer to the Black river in Wisconsin—and yet no cases arose. I take it from this that the factor of sufficient number of germs was lacking, further down the river due to dilution and probably the factor of loss of virulence by the spores being in that water also might be considered although I know that the loss of virulence cannot be a factor in this case because I know the bacteriologist, who still has water of that river which still proves infectious today when injected into animals, therefore I think I am safe in my first proposition that the principal factor
was probably that of lack of numbers. In other words,
7862 here the same as everywhere, it seems that the polluted
river spreading the water over both banks, only produced infections in the immediate neighborhood of the tannery where the number of disease germs must have been exceptionally great.

Q. How long ago was it that that epidemic broke out among the cattle in Wisconsin?

A. That is probably seven years ago.

Q. Assuming then that anthrax spores might pass through the Chicago drainage canal and reach the Mississippi river, what in your opinion would be the probability or possibility of the infection of cattle with Texas fever if they should drink the waters of that river below the mouth of the Illinois river?

A. Well, according to what I know of the literature of anthrax infections and the case I have just mentioned, I would say that there would be no danger of a direct anthrax infection by the drinking of that water at St. Louis.

Q. In view of the rigid inspection and strict regulations established and carried into effect by the government of the United States to prevent the spread of Texas fever, what in your opinion is the probability of anthrax spores ever getting into the Chicago drainage canal?

A. That is quite improbable with the thorough system of inspection—

7863 MR. JEFFRIES: I object to the question on the ground that it is immaterial, incompetent and irrelevant, and for the further reason that it assumes that originally inspection was made, when as a matter of fact common experience has shown that practically no inspection is made in various instance, and for the further reason that it has not been shown in evidence that any inspection whatever is made, and for the further reason that there is no evidence that the inspection if one is made, will be continued or effected, and for the further reason that there is no evidence showing the character of the inspection and no evidence showing that the inspection is sufficient to absolutely prevent the entrance or the carrying of anthrax or any other disease producing germ into the stock pens and slaughter houses, and for the further reason that this witness has not shown sufficient knowledge of the manner of inspection, if one is made, to be able to express an opinion in that respect.

Q. JUDGE SPRINGER: Answer the question.

A. From what I know with regard to this question, I think the inspection is a very thorough one by the government meat inspectors in the stook yards.

MR. JEFFRIES: I object to what the witness thinks.

THE WITNESS: Well, it is my opinion that it is a very—

7864 MR. JEFFRIES: I object to his expressing an opinion on that subject when it can be made a matter of proof.

Q. JUDGE SPRINGER: Have you had any opportnuities of examining personally the inspections that are made, there, or knowing personally what kind of inspections were made?

A. I know personally and in a general way the methods employed by the government meat inspectors at the stock yards in Chicago. I have learned those during a course which I have given some of those men in histopathology and bacteriology, and in that way I have learned the ways and means of preventing diseased meat getting into the market, or even diseased cattle getting into the slaughter houses, also the manner of disposal—

MR. JEFFRIES: I move to strike the answer out because it has no relevancy and carries no weight; it is incompetent and irrelevant, and all that the witness has said upon the subject has been gathered from hearsay and is hearsay testimony; that he knows nothing of his own knowledge and his own experience, and I move to strike out the answer and the question for the reason that he has eliminated the greatest source of anthrax infection, to-wit, the importation of hides and wool into the city of Chicago.

7865 Q. JUDGE SPRINGER: Assuming, professor, that tetanus spores should be deposited or get into the drainage canal, and should be carried by ice or otherwise, down the canal and into the Desplaines and Illinois rivers, and down to the Mississippi, river, would, in your opinion such spores be a menace or danger to the people who might use the water coming into the St. Louis intake at the chain of rocks, for drinking or domestic purposes?

MR. JEFFRIES: I object to the question for the reason that the witness is not a sanitarian and has had no experience upon the quantity of disease producing germs necessarily present in order to render themselves a menace and a detriment and a harm to the people drinking and using the water of a river for domestic purposes, and while the witness might from his bacteriological experience, be able to say whether or not a certain germ produces disease, and as to how long from his experience, certain disease germs might live under the laboratory experiments, the witness is not sufficiently experienced in sanitary matters to be able to judge from the experience of the civilized world and of the large cities, the amount of infected germs necessary to be present to render conditions harmful and deleterious and injurious to the health and life and property and business interests of a city and state.

7866 A. In answer to that question I will say that tetanus spores may remain alive in the sewers and drainage canal and river, but that the amount of tetanus spores entering the drainage canal and arriving at the intake channel at the chain of rocks in St. Louis, would be insignificant as compared with the amount of tetanus spores that would enter the river from all other sources along the river, the Illinois as well as the Mississippi and Missouri; further that the number of tetanus spores from Chicago sewage that would really be capable of entering the inlet at St. Louis, and would be absolutely insignificant as compared with the number already present in the streets of the City of St. Louis, as well as in any other city, or as well as in any other town all along the river.

7867 Q. What disease does the tetanus bacillus produce and how is that disease communicated?

A. Lockjaw and tetanus. The disease is communicated by the germs entering the tissues.

MR. JEFFRIES: I object to the question for the reason that it is not proper re-direct examination, the witness having testified that he discovered a tetanus germ or a spore in the waters of the Ilinois river in his direct-examination and all questions in reference thereto should have been asked of this witness at the time of his direct-examination.

JUDGE SPRINGER: This question is proper in my judgment for the reason that a great many questions were asked this witness on cross-examination, whereas, it is only incidentally referred to in the examination in chief.

A. With regard to the manner of the infection, briefly stated, it is necessary that the germ enter the tissues subcutaneously and at some depth, and that the wound be closed hermetically. Otherwise the germs cannot grow. The germ only

grows in the absence of oxygen. Therefore the germ must enter the tissues, usually by way of a deep wound, and that wound must close before the germ can grow. As soon as the germs grow they produce a toxin which when absorbed into the body, produces first conclusive movements of the muscles of the lower jaw, then of the upper extremities, then of the lower ex-
7868 tremities and finally death.

Q. Have you ever heard of a case of lockjaw being communicated by drinking water that contained tetanus germs?

A. I have never heard of any case of lockjaw being communicated by drinking any water.

Q. What in your opinion is the relative longevity of the typhoid bacillus, the cholera vibrio, the staphylococcus and the streptococcus in river water under similar conditions, and of the anthrax and tetanus bacilli not in spore form?

MR. JEFFRIES: I object to the question for the reason that the witness has stated that the science of bacteriology has been unable to prove the exact length of time that any of these disease producing organisms will live in a running stream, and I object to the question further for the reason that if it has not been determined by any science, that it is not aplicable to the Illinois river, the Desplaines river, the Mississippi river and the Chicago drainage canal, because inasmuch as experiments have been with reference to the water of that river. I object to the question for the further reason that the longevity of the disease producing organisms depends upon different conditions in various streams, and that it depends upon the different conditions throughout the year of the water in any particular stream. It depends upon the conditions of the water at flood times,
7869 the conditions of the water at low stages; it depends upon the temperature of the water with reference to the winter seasons and summer seasons; it depends upon the water that is discharged into the stream, whether discharged from the natural tributaries, or whether discharged by some artificial means, so that there is no known source of experiments, and there is nothing within the science of bacteriology that will enable any bacteriologist to state with any degree of accuracy, the length of time that the disease producing organisms referred to in the

question will live in the waters of the Drainage Canal, the Desplaines river, the Illinois river and the Mississippi river.

(Question repeated).

MR. JEFFRIES: I object to the question for the further reason that the water throughout all the stretches of the river from the very nature of things and from nature itself cannot at all times be similar and therefore it cannot be determined exactly how long the disease producing germs of the character mentioned in the question will not live, and how long they may not live and be alive, active and virulent.

A. Judge Springer, you simply want me to state how do the tetanus bacillus and the anthrax bacillus in the non-
7870 spore bearing form, compare in their longevity with the other bacteria, is that your question?

Q. Yes, under similar conditions in water?

A. If those bacteria are present in their non-spore bearing form, all I have stated with regard to the behavior of pathogenic bacteria in water, applies here, that is all I have stated with regard to pathogenic bacteria in general, leaving out the spores. As soon as those organisms form spores, then of course the spores are not subject to that general rule to which I have testified in the earlier examination.

Q. The question refers to what is the relative longevity of these respective organisms as compared to the typhoid bacillus?

MR. JEFFRIES: I make the same objection to this question that is made to the preceding question. I object to it for the reason that no examination has been made and no bacteriologist has as yet furnished any means of examining and ascertaining the behavior of pathogenic germs in a running stream, but that all of such examinations have been with reference to their behavior in the laboratory experiments.

Q. I find my question is incomplete, I will repeat it.
Would the typhoid bacillus live longer or die sooner than
7871 the other organisms mentioned in this question, if they
were placed in the waters of the drainage canal or the
Illinois river under similar conditions?

MR. JEFFRIES: I still object to the question for the same reasons stated above.

A. Tetanus bacilli as well as anthrax bacilli will die at least as soon if not sooner than the typhoid bacilli, in their non-spore bearing form under similar conditions.

Q. What as to the cholera vibrio?

A. The cholera vibrio dies sooner the lower the temperature.

Q. What as to the staphylococcus and streptococcus?

A. They die sooner than typhoid bacilli.

Q. State what organisms are spore bearing or spore producing?

A. Of the pathogenic germs?

Q. Yes?

A. The anthrax bacillus, the tetanus bacillus, malignant oedema, the bacillus aerogenes capsulatus. Of the important disease producing bacteria, these are the ones.

Q. Now, professor, assuming there is a remote possibility that a tetanus spore might be carried from Chicago through the drainage canal and down the Desplaines, and Illinois rivers and
a possibility that such a spore might enter the St. Louis
7872 intake and the hydrants of the St. Louis waterworks, and
the possibility that a St. Louis urchin might moisten his finger with water and then shoot a wad into his finger, thus moistened as aforesaid, as stated by Mr. Jeffries in one of his hypothetical questions, and that such moisture may contain a Chicago tetanus spore, as assumed in one of the other questions by Mr. Jeffries, and that such tetanus spore thus sub-cutaneously injected into the finger of said urchin may have entered the anatomy of said urchin at a time when his system was susceptible to tetanus infection, and the possibility that said St. Louis urchin might then and there contract the disease of lock jaw;—are such remote possibilities as I have mentioned, in your opinion as a bacteriologist, of such a grave and serious character as to constitute a menace or danger to the inhabitants of St. Louis or of the State of Missouri?

MR. JEFFRIES: I object to the question for the reason, first that the opportunities and abilities for the infection are not remote, are not impossible and are not improbable under the assumptions contained in the question, and that the question as to the remoteness, improbability or impossibility, is one for

the Court to consider, and not for this witness. I also object to the question for the reason that it is not for the witness to say that the infection of tetanus caused by the one germ
7873 being injected into the foot of the street urchin, in St. Louis, is not a menace to that city. Upon the other hand I insist that under the assumptions contained in the question, that if such occurred it would be a menace and would be liable to lead to other cases of tetanus, and that if such be true, and that if such conditions should exist under the assumptions of the question, judgment for complainant should go. I object to the question for the further reason that the witness is not a sanitarian and it is not for him to say, not having qualified upon that subject, whether one tetanus germ, two tetanus germs, a hundred or a thousand are necessary to be found in the water supply of the city of St. Louis in order to render it in such a condition that it would be a menace to the people of that city.

JUDGE SPRINGER: I desire to suggest to counsel that the question is not put to him to be answered, and suggest that that part of his objection which answers the question is not proper. The witness is asked to state whether it would be a menace and not the counsel on the other side.

MR. JEFFRIES: I am addressing myself to the Court and not to the witness.

JUDGE SPRINGER: You are answering as a witness that it would not be a menace, which question is not put to you.

7874 MR. JEFFRIES: I insist, Judge Springer, that my objection is addressed to the Court; not to counsel and not to the witness.

THE WITNESS: I will have to answer that question with No. Tetanus infection takes place when street dirt or garden earth, containing numerous virulent germs, enters the deeper tissues and not by water as stated.

RE-CROSS-EXAMINATION by Mr. Jeffries.

Q. Professor, speaking now of the frozen condition of the water in the Illinois river, under the assumptions contained in the questions propounded to you by judge Springer in the re-direct examination, you made a statement, I believe that bacteria would not freeze in the ice as long as they possibly could avoid it themselves, in other words that they would swim away from the place where the ice was forming, into the warmer water. Now then I want to know, having the ability to swim away from the ice or the point where the ice is being formed, is it not reasonable to believe also that they will swim away from the light as far as they can, that they will swim away from the saprophytic bacteria and from all other material and from all other conditions that will not be conducive to their welfare and their longevity; isn't that true? Just answer that question. 7875

A. That is no doubt true.

Q. Then, professor, will they not also when swimming away from the formation of the ice, swim into the water and be carried down underneath the ice with the rapidly flowing current under the ice, isn't that true?

A. They will not move large distances, their motility is not as great as that.

Q. As they swim away from the point where the water is frozen they are carried by the current itself without any action on their part, down the river, aren't they?

A. According to the current that happens to exist.

Q. Then professor, if that ice is formed over the whole bed of the river and remains there from six to eight weeks, and if the conditions of the water are such as will permit the typhoid bacilli to live from ten to twenty days or thirty days in that cold water underneath the ice and it only requires either ten or twelve days for the water to go from Chicago to St. Louis, is it not altogether reasonable to believe that these germs will find their way during their life time down the entire course of the Illinois river?

7876 JUDGE SPRINGER: I object to this question for the reason that it assumes that typhoid germs will live in that water, in the Illinois river and drainage canal for ten or twelve days.

A. If the bacilli would live at these lower temperatures without dying, and would be alive in St. Louis, of course.

Q. That is, if they would live that long?

A. That is your assumption.

Q. And whether they would travel that distance in that time, they would pass down.

A. That is your assumption, although the conditions are not such.

Q. Conceding that the assumptions are true; in other words that they will live that long and in other words assuming that the water would pass down in that period, they would arrive there?

A. If the lower temperature and saprophytic products had not entirely exterminated them they would arrive there.

Q. In answer to a question propounded to you by Judge Springer, in which it was assumed that ice was formed in the drainage canal, the Desplaines and the Illinois river, and that it remained frozen from six to eight weeks, and that in the spring of the year, when the ice broke up it was carried out, whether or not they would arrive in the Mississippi river
7877 and the chain of rocks alive, and in your answer you stated
that you did not believe they would be alive on their arrival in the Mississippi river, and I want to ask you if it is not a fact that experiments on typhoid fever in ice, have shown that some typhoid germs may live for three months in ice?

A. It is my opinion, and, in fact, some of my testimony has been to the effect, that typhoid bacilli could live in the absence of other bacteria in water and also in ice for a long time, but I see that some experimenters have come to different conclusions with regard to that. Some have come to the conclusion that a very low temperature, such as the temperature of ice, destroys the typhoid bacilli very quickly, so I have answered Judge Springer's question with that in view, that they can live six to eight weeks, knowing that some experimenters have found it so. The cholera vibrio died in two days in ice.

Q. We are speaking of typhoid?

A. Yes, but I am now taking everything into consideration by analogy. The resistance of the one germ is not so much greater than that of the other, but everything considered, it is not unlikely that some of the germs would not live longer than thirty days or six or eight weeks, in the ice.

Q. Would you consider it unlikely that they would live that long, that some of them would?

7878 A. According to some experimenters they have lived longer in ice.

Q. Then professor, is it not a question which cannot be determined, as to the exact length of time which they will live and as to the exact time in which they are all eliminated from life in the ice?

A. It has not been definitely determined, if we take all the evidence from all sides. Some find they die in a short time, others say they only die in great numbers, but some of them remain alive for a longer time. It has not been definitely determined.

Q. So that yet it has not been determined?

A. No sir. That is, there is a difference of opinion.

Q. Then taking those conditions to be true, that they do live in ice and that the time in which they live in ice has not as yet been determined, may not large quantities of them remain longer than thirty days, while it is true that large quantities may also die in that time?

A. No, that is not true. Large quantities will not remain. The majority of them will die, even according to the experimenters that say that some remain alive.

Q. But the percentage that will remain alive, cannot be determined?

7879 A. It is an insignificant one.

Q. In your judgment?

A. According to their findings.

Q. Professor, in reference to this epidemic of anthrax, or infection by anthrax, in Wisconsin I believe it was?

A. Yes sir.

Q. Do you know whether or not there were any precautions taken by the people living below the place of infection to avoid that disease or to keep that disease out of the cattle?

A. There were no precautions taken of any kind.

Q. That you know of?

A. I know that there were none taken; I know all the details of that.

Q. Professor, you know, do you not, that competent observers have found the spore of anthrax live in water for seven years?

A. For years. The spore of anthrax can no doubt live for years.

Q. Profesor, you testified I believe that unless the germs or spores of anthrax were very numerous, there could, as in the case of typhoid be no direct infection from water?

JUDGE SPRINGER: You mean by drinking spores?

MR. JEFFRIES: Yes.

7880 A. Well, in that respect I will say that I realize fully that it takes a very minute quantity of anthrax material to produce an infection, but I have taken into consideration the history of epidemics where we know there must have been large quantities of the infectious material polluting a river and where we know that the material was spread over meadows and eaten by cattle and sheep which promptly died. In such cases we hear of no anthrax infections a few miles down the river. Knowing that the spores can live for years and also knowing that such spores certainly must be in the water and upon the overflowed shores of this river for longer distances, although only the animals near the original source of pollution die of anthrax infection, I conclude that the factor here, that was lacking, was the necessary number to infect.

Q. May it not professor, depend upon the fact that no animal whose system was in a proper condition, swallowed one of those spores?

A. Then they shouldn't have all died nearer the source of infection there, whereas no deaths occurred further down the river.

Q. May it not have been professor, that the source of infection, that one animal, the system of which was in a proper condition to produce a colony or large quantities of the germs, until the disease overtook the system and the animal finally died, and that animal in turn infected the whole herd, and the whole neighborhood?

7881 A. Well that is another way of infection.

Q. May not that also be done?

A. That may also be done.

Q. Now then, professor, may not the absence of the infection farther down have been brought about by reason of the fact that no animal, either a sheep or a cow, drank or carried into its system, an anthrax spore, with the system of the animal in proper condition to produce and develop the disease?

A. That is possible, but the history of the case that was stated here, is that all animals eating of the same food, from the same overflowed meadow, died of anthrax. It was not one animal that died, but all the animals on pastures bordering the river at its source of pollution died. It was evident that an infection had taken place by a sufficient number of virulent bacteria.

Q. Granting that to be true, professor, and that it may happen in certain cases, may it not also be true that the one animal in the first instance may have carried into its system one spore from the meadow, or from its food, and that its system was in such a condition as to grow anthrax and produce large quantities of it, and that the discharges from that animal went over the field and meadow and place where the other cattle
7882 were feeding, so that the whole herd became infected,
and from that herd other herds and so on?

A. That is another manner of infection and a very common one, and finally the animal is transferred to some other locality and an epidemic of anthrax starts there.

Q. Now I would like to have you describe professor, as accurately as you can, this epidemic of anthrax that took place up in Wisconsin that you referred to in your re-direct examination?

A. This epidemic originated near a tannery in Medford, Wisconsin. Some of the hides used came from Brazil and from China, by the experiments, I believe of Professor Russel, these hides were found to contain anthrax spores. A number of animals just below the tannery had suddenly died and practically all at the same time on the meadows immediately below this tannery. The Black River received the sewage of the tannery and had shortly before overflowed the meadows on both shores of this river. In fact the whole epidemic came suddenly amongst the cattle on the banks of the river, and there was much apprehension among the farmers farther down the river because it had also flooded its banks there. I have a farm a few miles below this tannery on this river and my neighbors were of course also very much alarmed. Their cattle were usually on

my land, which is simply wild woods, the river crossing it,
7883 on both banks of the river there are openings, where
the cattle of the whole neighborhood is grazing, because this wooded land is not fenced in, consisting of virgin forests, whereas all the surrounding land is cleared up. All the herds of the neighbors around there have been grazing on the banks of the river on my lands which are frequently overflood. This is only a few miles below the tannery but none of these animals died whereas horses, cattle and sheep died just below that tannery. Horses of farmers living within a distance of half a mile or a mile died. Lawsuits followed by many of the people living below the tannery. This matter was investigated by Professor Russell of Madison, Wisconsin, as the State Bacteriologist. He found anthrax spores in the water of this Black river below the tannery and he has yet water specimens in his laboratory which when injected into animals produce anthrax showing that there are still virulent spores present. This is now a number of years ago. During all these years there has been no death of any animal, I think I may safely say, one mile below this tannery or farther down the river. This is such a striking case
7884 where water can be shown to contain virulent spores and
retain them for many years, and yet farther down the river not an animal dies, in spite of the fact that there must have ben a tremendous pollution with anthrax material, of that river.

JUDGE SPRINGER: How far is Medford from the mouth of the Black river?

A. Why this tannery is in Medford just south of the city, and the City of Medford is on the banks of Black river. The tannery is located directly on the banks of the river and emptied its refuse into the Black River at the time of this epidemic.

Q. How far is it from the town of Medford to the mouth of the river where it empties into the Mississippi?

A. I don't know.

Q. It empties into the Mississippi, doesn't it?

A. It empties into the Mississippi at La Crosse, I believe. The name of the stream is Black river. It passes through Medford. My land is about five miles from the city.

Q. MR. JEFFRIES. Professor, even though it did not continue to spread, may it not have been the peculair character of the spore which was weakened on account of its long travel or journey, or its surrounding conditions, or its origin, so as not to be as effective, and strong and healthy and virulent, as other spores in other epidemics, or as it might be at another time? 7885

A. Yes, that would be another factor. Aside from the factor of the number, we have the factor of virulence to consider.

Q. And on the journey from China?

A. And on the journey, but this loss of virulence doesn't seem to have taken place in Professor Russell's samples of water which are still virulent today.

Q. But that water was taken at the time the epidemic was going on?

A. Yes, that was taken at a time when a number of the cattle died.

Q. And in testing the virulence of the spores in samples of water today they probably used more susceptibile animals?

A. Yes they used guinea pigs which are very susceptible. I don't know whether Professor Russell has tried this on any sheep or cattle, but when we speak of virulence, we usually mean virulent to laboratory animals, guinea pig, rabbit, and mouse.

Q. So then it may have been of such a character as to have lost its virulence as applied to sheep and cattle?

A. It may.

7886 Q. Professor, do you know whether or not the spore of anthrax will multiply under favorable conditions in the food?

A. Yes sir.

Q. And in the fodder and corn and grain and shipping stuff or whatever may be used?

A. The anthrax spore will under favorable conditions of temperature, and of food multiply.

Q. At what temperature?

A. The most favorable temperature is that of the human body, at which it grows best.

Q. Will the typhoid germ multiply at a lesser temperature?

A. They can multiply at a lower temperature.

Q. Then professor, may not these spores find their way from the fields into the hay-mow, or the corn-bin or the oat bin, and in the preparation of the food, in the mixture of the food find their way into the food and in the summer time in the pasture and in the field, and in the feed troughs, conditions be brought about like this in reference to the increase in the typhoid germs, isn't that true?

A. Yes, I think anthrax spores may find conditions favorable for again multiplying.

7887 Q So that under favorable conditions professor, an infection will take place in an indirect manner?

A. Although we know of no such infection.

Q. May not, professor, the first animal at Medford, have been infected in that very way? In other words, isn't it altogether a question that has not as yet been fully determined?

A. Yes. I should perhaps in this case state the fact that the first case of anthrax that died in Medford was a human being; it was one of the scrapers in the tannery. The scraper is a person who scrapes the hair from the hide after it has gone through a process of fermentation in the sweat house, where a strong odor of ammonia is produced, and the hairs become loosened. The hides then go upon a wood block and the scraper allows a stream of water to run over this hide, while he scrapes off the hairs. If he has wounds, or if he wipes his fingers over his lips he becomes infected or developes intestinal anthrax. I know of at least one case, although there have been a number of mysterious deaths, but in one case that I have examined, I feel certain that it was the cause of the death although doubted at the time because no autopsy was held. The patient had 7888 gone to his work in the morning as usual, came home at two o'clock and died without other symptoms except some fever, slight headache and general malaise. It was the first case of anthrax in Medford. The deaths of the cattle followed later, investigated and diagnosed by the State authorities as anthrax.

JUDGE SPRINGER: How long after this man was supposed to have been infected, was it that he died?

A. The man was not sick long because he went to his work in the morning and went home at two o'clock and died. It is one of those mysterious deaths that happen so frequently in tanneries in the United States, which no doubt are cases of anthrax Bacteremia. In this case there is no doubt at all that the primary infection was simply carried by the hides from the sweat house, where they multiplied to the river. The river was polluted with anthrax spores and overflowed the banks, causing infections of cattle near the tannery but none further down the river.

Q. And that cannot be accounted for, first because of no direct infection, and second, because of the loss of 7889 strength and virulence?

A. Well, as to the loss of virulence, they are still virulent today, those spores in the water.

Q. But as to the loss of virulence in the germs, after it had been deposited in the soil and on the earth, and also those that are preserved today, they may have a loss of virulence because while they may be able to produce infection in guinea pigs, yet they might not in animals such as a cow or a sheep or a horse?

A. That might be, although when we see a guinea pig die in 24 hours after inoculation of a minute quantity of material, we take it for granted that it is virulent, and will be virulent to man, or virulent to animals, the other factors being right.

Q. There is none of your land under cultivation?

A. No sir, it is just wild woods.

Q. I want to ask you this question. In the case of anthrax it matters not where it may be, if the water infected with the spores should find its way upon the meadows, corn fields, wheat fields and cultivated land and be deposited there upon the receding of the water, that they might not in turn find their way into the haymow, into the corn bin, oat bin, feed bin, and be mingled with the food preparation, and that in the summer time, with that preparation, get into such a condition, either on 7890 account of the water from the horses, mouths, or the water that is poured into the feed of this preparation, that it would produce conditions that would be conducive to the growth and multiplication of the anthrax and that in turn might not produce the disease of anthrax in the animal eating it or swallowing it any time within the life of the germ, from one to seven years or whatever time they may live?

A. As to anthrax spores I can say that it is probable that they die under the usual conditions of exposure in water as well as on the ground, after being exposed to the sun and the air for a long time, but the possibility exists of them living for a long time and when they find a favorable culture medium and temperature they can, of course, increase, and they may then, or may not be virulent after they have increased.

Q. Assuming there was annually a daily receipt of 30,000 head of sheep in the stock yards and slaughtering houses of the city of Chicago and assuming that there is an annual daily receipt of 20,000 head of cattle and that these cattle and sheep are slaughtered and prepared for consumption, in the slaughtering houses of the city of Chicago and assuming that said cattle and sheep are shipped to Chicago from various surrounding towns, do you not consider it probable and possible that
7891 the germs of anthrax may be carried into the stock yards and slaughtering houses in the hair and wool of the cattle and sheep and discharged into the drainage canal and thence into the Illinois river?

A. Such a condition is possible, but it exists all along the Illinois river.

Q. Now professor, assuming that there are a large number of tanneries and brush factories in the city of Chicago, state whether or not those establishments may not be a source of pollution by anthrax?

A. If the brushes that are made come from infected animals, the bristles are liable to contain the spores of anthrax.

Q. How about the tanneries?

A. In the tanneries, the hides of infected animals that have been killed and have escaped detection in government inspection, I think the government has recently taken steps to prevent the entrance of suspected hides—

Q. That is in reference to the imported hides?

A. Yes sir.

Q. But that doesn't apply to the domestic hides?

A. No, the domestic hides are not supposed to have anthrax.

Q. But they may have?

A. Yes, they may have.

7892 Q. And often times do?

A. And often times do. I believe there is a little town here in the state of Illinois that has had an anthrax epidemic and may be sending their water into the Mississippi. It is Palatine, Illinois. There is government inspection at the various slaughtering establishments in the city.

Q. Anthrax may be carried in the wool of sheep might it not?

A. Yes sir.

Q. Professor, is Professor Rubner, to whom you have referred in your re-direct examination and in your testimony in this case a bacteriologist?

A. Every institute of hygiene in Germany has as its most important branch a bacteriological laboratory and a chemical laboratory.

Q. But do you know that he is a practical actual bacteriologist, or in other words, isn't he just simply a professor of hygiene?

A. The modern sanitarian assumes to be a perfect bacteriologist and I think he ought to be and he certainly is entitled to be considered so, and, therefore, I think Rubner is entitled to the same credit.

Q. But you cannot say that you know that he is an actual practicing bacteriologist?

7893 A. I think it is safe to say that the opinion of Rubner on bacteriological questions, is as valuable as those of any bacteriologist, in matters of sanitary importance.

Q. Do you know whether or not he is a bacteriologist?

A. He must be or he could not be professor of hygiene and director of the hygienic institute in Berlin.

Q. But professor, aside from what in your judgment is required of a man to occupy that position, and without knowing, do you know whether or not he is an actual practicing experimental bacteriologist?

A. He, no doubt, does not do much of the bacteriological work himself any more.

Q. Do you know of your knowledge that he ever did any of it?

A. I think I am safe in saying that he could not occupy the position he does, if he was not thoroughly proficient in bacteriology.

Q. Now is it not a fact, professor, that you do not know whether he is or ever has been an actual practicing, experimental bacteriologist?

A. No, the opposite even is true. I know that the Hygiene Institute in Berlin has a bacteriological as well as a chemical laboratory, in which most thorough work has been done 7894 and is being done.

Q. I am not talking about what is being done there, but about what Professor Rubner has been doing. Now then, isn't it a fact that he is not an actual, experienced bacteriologist, and if he is not a bacteriologist, isn't an authority on the longevity of bacteria.

A. I think by his studies in the bacteriological laboratory he would be entitled to be considered an authority with regard to the life of those bacteria, on which he has expressed an opinion.

Q. Now professor, is not tetanus the disease to which both man and animals are subject?

A. Yes sir.

Q. Now assuming that the germs of anthrax are deposited into the Illinois river by means of the Chicago drainage canal and that they flow down the Illinois river into the Mississippi and that being discharged into the Mississippi river in high flood times, they are carried by the waters of that river into the low-lands along said river, into the various river counties of the State of Missouri below the mouth of the Illinois river, and are deposited there upon the earth, weeds, grass and growing substances, and assume that after the water has receded, leaving the anthrax germs on the soil and vegetation, that 7895 by some means these anthrax spores are carried into the food preparation, which is brought to a temperature favorable for the multiplication of the anthrax spore, and the cattle and horses and sheep of said counties should feed upon such food when reduced to such a temperature as would produce a multiplication of the spores, there being present, would they not and might they not be infected with the disease of anthrax.

Assuming those conditions to be true, I want you to answer the question.

A. The remote possibility exists, although all the history with regard to epidemics of anthrax, and their spread, would be opposed to the spread of anthrax in that way.

Q. Professor, assuming that you visited the stock yards of Chicago or the slaughtering pens of Chicago or the tanneries or the brush factories of Chicago and collected a quantity of anthrax spores. In the course of a month, two months, three months, four months or a year, you scattered those spores on the surface of the soil in one of the counties of Missouri, in the southeastern part of the State that overflows from the water of the Mississippi river. Those spores are gathered on the grass and carried into the barns and enter into the preparation of the food that is fed to the cattle, the sheep and horses, upon the farms of southeast Missouri, and in the preparation 7896 of the food a temperature is produced that will favor the multiplication of the germs of anthrax from that spore. State whether or not under those assumptions, the disease of anthrax might not be produced in those animals so eating the food prepared in that way, and under the conditions assumed in the question, even though there should be but one spore of a number of spores so carried by you, that would find its way into the food preparation at a favorable temperature?

A. I think I have already stated before that it is my opinion that we would never hear of those spores again.

Q. Professor, we are talking about the spores that you collected at Chicago and took down there and distributed on the grass and meadows, and that one of them finds its way into the food under the conditions assumed in the question, whether under the assumptions that would produce anthrax?

A. That is what I mean. We would never hear of those spores again; they would never produce anything, even if they had been spread in large numbers. I reason again by analogy, according to the history of epidemics of anthrax where we know that large quantities have been spread over large districts, and you never hear of them again.

Q. That it has lost its virulence because of that?

A. It must have lost its virulence, or the number of

7897 spores is not sufficient. The individual germ will not produce infection.

Q. Now if that be true, why is it that those hides could be shipped from Japan to the little city of Medford and still produce disease?

A. Because they were there in immense numbers and multiplied in the sweat houses. An animal that has died of anthrax, has every blood vessel of the body filled with anthrax bacilli, as we have in no other bacterial infection.

Q. Do you mean to say then that you could not in your laboratory or under the proper conditions in the food of the animal take a spore of anthrax and cultivate a sufficient quantity to infect a whole herd of animals, do you assume that position?

JUDGE SPRINGER: I object to that; he hasn't assumed that.

MR. JEFFRIES: There is one thing true, and that is that anthrax is either contracted directly or it is contracted by indirect infection and unless it can be contracted in one of the two ways, then there is absolutely nothing to the proposition that anthrax is a disease producing germ.

A. There is a great difference between numbers of bac-
7898 teria in a hide which comes from an animal infected with anthrax, teeming with millions and millions of spores, and the distributed product in nature, on earth and in water, where great dilution and competition with other bacteria occurs.

Q. Professor, may not the epidemic of anthrax at Medford, to which you have testified, been caused by one spore falling from the hide, or one hide that was shipped from Brazil or Valparaiso, or elsewhere to Medford, by it having been injected into the proper media?

A. The possibility exists, but it is not probable.

Q. With the proper culture media?

A. I say the possibility exists, but it is not probable.

Q. Then professor, what is there in the theory of indirect infection?

A. I say the possibility exists but it is not as probable as is the case with the typhoid bacillus.

Q. Professor, if the theory of bacteriologists and sanitarians is true, that the disease is produced in an indirect manner

and the infection brought about in an indirect manner, is it not intirely probable and reasonable to believe that one of the spores that is carried from the tanneries of Chicago to the proper food media in one of the southeastern counties of Missouri might not produce a culture of anthrax germ and
7899 produce disease?

A. I say it is possible.

Q. Is it not reasonable to believe that if it was transplanted, assuming that it is, assuming that you have transplanted it yourself to the food and that the food will be a proper media, and at a proper temperature to bring about a multiplication of the germs, that it will produce disease, isn't that true?

A. It is possible.

Q. Isn't it probable and isn't it reasonable to believe it?

A. No.

Q. Now professor, we are taking an experiment of your own, a laboratory experiment for instance. You go to the tanneries of Chicago. You find a hide that you know is infected with anthrax. You get a spore that is alive and virulent; you carry that to Southeast Missouri to a food preparation, and you reduce that food preparation to the proper temperature that would bring about a multiplication of the germs. Now if that spore was alive and active and it produced a large number of spores upon that media, wouldn't that produce an infection of the disease?

JUDGE SPRINGER: I object to this question and to the preceding one of a similar nature, because it assumes a fact that can never take place, namely; that this witness would deliberately carry an anthrax spore from Chicago to Southeast
7900 Missouri and plant it there, where it would become a matter of infection to cattle and horses, or that any such condition is likely to arise on account of the well known good character of this witness.

MR. JEFFRIES: Well, that may be true, as far as the physical conduct of the witness himself is concerned, yet we ask the question in the form presented, because it is as near a practical, actual laboratory experiment, and is as close to nature and so closely associated and related to nature, that it is competent as such, and for the further reason that the question as stated comes nearer to what takes place in nature than to what takes place in the laboratory.

A. It is possible under the usual conditions of infection, but not as probable as in the case of the typhoid bacillus.

Q. You say it is possible. I want to know if as a bacteriologist, you do not consider it reasonable on the theory of indirect infection?

A. It is even reasonable under the conditions which usually govern direct infection, that is, first, that the germ is present; second, that it be virulent; third, it is necessary that it finds the proper temperature for its rapid multiplication, and fourth, that the animal infected shall have the necessary reduced resistant forces, and fifth, it is necessary that the animal receive a sufficient number of these germs to produce infection.

7901 F. ROBERT ZEIT.

ADJOURNED until 10:00 A. M. Friday, October 9, 1903.

7902 10:00 A. M., Friday, October 9th, 1903. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

ADOLPH GEHRMANN,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer, and testified as follows:

Q. Will you please state your name, residence and occupation?

A. My name is Adolph Gehrmann, residence Chicago, occupation physician.

Q. You might give your address.

A. 3816 Ellis Avenue is my residence address.

Q. And occupation physician?

A. Physician and bacteriologist.

Q. State what positions you have occupied in reference to scientific matters?

A. Do I understand, public positions now?

Q. Yes sir.

A. From the year 1893 I was connected with the Chicago

7903 Department of Health in the capacity of bacteriologist and microscopist for the milk department, during 1893, and from January, 1894 until June, 1902, as the director of the laboratory and bacteriologist of the department.

Q. From what time?

A. From January, 1894 until June, 1902.

Q. Where were you educated, doctor?

A. I received the ordinary high school education in Chicago and entered the Chicago Medical College, the Medical Department of the Northwestern University and was graduated with the degree of doctor of medicine in 1890. Since then I have studied in this country and to some extent abroad.

Q. Have you ever taught chemistry or bacteriology in any of the institutions of this country,—or hygiene?

A. I have taught bacteriology and hygiene in the College of Physicians and Surgeons.

Q. Where is that?

A. The medical department of the University of Illinois, in Chicago. My connection there began in the spring of 1892, and continues up to the present time.

Q. What was the nature of the text books that you taught at that time, what kind of text books were you using and teaching from at that time?

A. Text books used in our work?

7904 Q. Yes.

A. We were using the most recent editions of the text books on bacteriology and hygiene, at different times,—changing from time to time.

Q. Have you taught in any other institution or institutions?

A. I am now connected as professor of hygiene in the Dearborn Medical college.

Q. In this city?

A. At Chicago; and as professor of Bacteriology in the Harvey Medical College in Chicago.

Q. How long have you been connected with those two institutions?

A. Well, in Harvey Medical College, about a year and a half; the other school is a new school, that is just started, so it is only a few months.

Q. Are you still engaged with any institutions as a teacher upon any of these subjects?

A. I have all of these connections now.

Q. Then you have been engaged in teaching what branches and for what length of time?

A. I have been teaching bacteriology for eleven years, and hygiene for about eight years.

7905 Q. As a teacher of hygiene and bacteriology, and as a graduate of a medical college, and as a professor of medicine, have you given any special attention to the causes of diseases of the human race?

A. Yes, that has been a part of my daily work.

Q. What was the nature of your employment and what were your duties when you were connected with the health department of the city of Chicago?

A. It was the conduct of the laboratory for chemical and bacterial examinations and the making of bacteriologic examinations,—particularly as a bacteriologist. Those were my duties.

Q. Of what waters?

A. Well, there was no question as to waters—

Q. Well I now put the question. I say, what were the waters that you were examining chemically and bacteriologically in the health department of the city of Chicago?

MR. JEFFRIES: I understood the witness to say that he examined no waters.

A. No, I did not. The question was asked what were my general duties. I anwsered that they were general supervision of the laboratory, and the conduct of the bacteriologic work in particular. Now if there is another question I will answer that.

7906 Q. JUDGE SPRINGER: Where were the samples of water obtained,of which you made bacterial examinations?

A. The laboratory received samples from a number of different places, that is—we were continuously making examinations of water samples from the city water supply, were a large part of the number of samples of water. The samples of water were from places where ice was obtained, connected with farms from which milk was supplied from time to time, and for a period, samples of water from the Illinois and Michigan

Canal, the Illinois and Desplaines rivers and tributaries and the Mississippi and Missouri rivers.

Q. State how frequently samples of water were taken from Lake Michigan, if any?

A. During the year 1893, a weekly examination of the water was made from Lake Michigan, from the four tunnels, in use, and the water supply as delivered in the laboratory, making five samples per week, in 1893.

Q. From what places?

A. Do you want the name of the tunnels?

Q. Yes?

A. Well there was the Lake View tunnel, the Chicago Avenue tunnel, the Fourteenth Street tunnel and the Sixty-eighth Street tunnel.

7907 Q. Where did you obtain the samples at the point of intake of the tunnel or at the shore end of the tunnel?

A. These samples were taken at the shore end of these tunnels, except the one which was taken in the laboratory, which was takn from the tap in the laboratory.

Q. Yes, from the laboratory tap?

A. Yés. From the beginning of 1894 on, to as long as I was connected with the work, these samples were taken daily for every working day. The laboratory tap sample was discontinued some time during 1897, and later there were some additional samples added,—added territory, such as Rogers Park was added. There were occasional samples from the added territory west of the city, Austin, and a sample from the new tunnel that was constructed from Oak Street, known as the Carter H. Harrison Tunnel or Crib. These later ones were not daily samples; they were taken bi-weekly or every other day.

Q. Who made the chemical analyses of those samples taken during the period when you were director of the Chicago laboratory?

A. During 1893, 1894, 1895 and part of 1896, Mr. Cass L. Kennicott was the city chemist and made the chemical examinations. From that time on until January, 1900, Mr. D. B. Bisbee was the city chemist and made the examinations.

7908 During 1900, Mr. W. L. Maharg—I think his name is, was the city chemist, and made the examinations, and from

1901 again, Mr. Bisbee was the city chemist and made the examinations.

Q. There were two persons by the name of Bisbee?

A. No, D. B. Bisbee was his name.

Q. I thought you mentioned Bisbee a little while ago, the first man after Kennicott?

A. Well that was Bisbee.

Q. . The same person?

A. Yes, that is the same man.

Q. He dropped off for a time then according to your statement?

A. Yes, during 1900, he was away, at least part of the year, I don't remember the exact date.

Q. State in what manner the results of these chemical and bacterial examinations were entered of record, and whether they were published as a part of the health reports of the city of Chicago?

A. The examinations daily were recorded in series and arranged by months. The work of each month was tabulated together, averages were drawn, and with the reports that were published from the department a large number of the records for the months were published in detail. They were not all published up to date.

7909 MR. JEFFRIES: For the months?

A. Yes, these monthly records were published in a number of the reports but they have not all been published up to date, there are one or two years left out.

Q. JUDGE SPRINGER: Those that were published are they contained in the printed reports issued by the Board of Health of the City of Chicago?

A. Yes, those which were published are in the reports published by the department.

Q. What was the object of taking the samples, making these analyses and publishing them in said reports?

A. The object of such work was to learn as to the conditions that could be ascertained from bacterial and chemical examinations of the water, as to its quality.

Q. And bacterial also?

A. Yes, I said, chemical and bacterial also.

Q. How long since you ceased to be connected with the health department?

A. I left the service of the health department in June, 1902.

Q. Do you hold any official position at this time in the city government?

A. No.

7910 Q. 1902 is when you ceased?

A. Yes.

Q. Or in the government of the state?

A. No, not in the state.

Q. Or in the general government, the national government?

A. No.

Q. Were you at any time called upon to make bacterial examination of waters from the Illinois and Michigan canal, the drainage canal the Illinois and other rivers in this state?

A. Yes sir.

Q. When was that?

A. In the early months of 1899, I was instructed by the Commissioner of Health of the city of Chicago to arrange for the examination of samples from the Illinois and Michigan canal, the Desplaines river, the Illinois river and its tributaries, and the Mississippi and Missouri rivers, and attended a number of conferences with Professors Palmer and Burrill of the University of Illinois and Professor Jordan of the University of Chicago.

Q. What was the object of those conferences, and what work if any, did they bring about?

A. The object of these conferences was for the purpose of laying out a plan for the collection of samples and the 7911 chemical and bacterial examination of the same at points as before stated, and to arrange for the details of such an investigation.

Q. What particular points were established in reference to the investigation which was to be made? I do not have reference to the places, but I mean the subject matter, or detail of your investigation, what was the scope of it?

A. These conferences were to settle first, the localities in which the samples would be collected; second, all matters relating to the exact points in the rivers from which samples would be taken, and the selection of the collectors to be left to the mutual agreement of Professors Jordan and Palmer. The arrangements for the transportation of the samples and the equipment of the collectors with outfits to be conducted by the Health Deparment laboratory. It was decided as to the outfits to be used by the collectors,—

Q. What did that embrace?

A. That embraced the cases in which the bottles would be shipped, the bottles themselves, the necessary labels, tags and matters of that kind.

MR. JEFFRIES: I object to the witness stating what was decided to be done. Let him state what was done.

7912 Q. JUDGE SPRINGER: Well, what was done?

A. I am stating now what was done. These are the things that were done.

Q. You not only decided to do these things, but you did them I understand?

A. Yes. One more. It was agreed to, a summary of procedures as to the methods to be used in making the examinations.

Q. How many places were agreed upon for the purpose of making the chemical and bacterial examinations,—chemical analyses and bacterial examinations?

A. At this time, forty—

Q. No, I mean the laboratories?

A. Three laboratories were engaged in the investigation.

Q. What were they?

A. The laboratory of the University of Illinois, the laboratory of the University of Chicago, and the Health Department of the city of Chicago.

Q. What was the character of the work done at the Chicago laboratory under your charge, generally speaking, in regard to these samples?

A. Oh, a chemical and bacteriologic examination was made of the samples.

Q. The samples that came to you under this arrangement?

7913 A. Yes sir.

Q. Who conducted those examinations?

A. The chemical examination was conducted by Mr. D. B. Bisbee, and the bacteriological examinations were conducted by myself.

Q. Was it understood at that time that similar analyses and examinations were to be made at the other two places that you mentioned?

A. Yes sir.

MR. JEFFRIES: I object to the question and object to the witness stating what he understood was to be done. He should state what was done.

JUDGE SPRINGER: This witness has stated that he met these three gentlemen and they agreed on a program of operations.

MR. JEFFRIES: I don't see what effect their understanding would have upon the work done in this case. This man cannot testify as to what the others did.

JUDGE SPRINGER: He can testify that they were to make those examinations at their places, and he was to make it here. Now then I will let him tell what he did, and let them tell what they did when they come on the stand. It is simply a matter of detail.

7914 MR. JEFFRIES: All right.

Q. JUDGE SPRINGER: Now then, professor, you may state what arrangements you made and carried out as chief of the health department laboratory, after the taking of these samples, their transportation to the places indicated and their analyses and examinations thereafter?

MR. JEFFRIES: Now do I understand that question to relate back to 1894, and down to the present time?

JUDGE SPRINGER: It relates to the times when it was done. He has given the time before.

MR. JEFFRIES: Yes, but he has testified that he made examinations of the Illinois river, Lake Michigan as far back as 1894. Now this arrangement about which he has been speaking, made with these other gentlemen of these other institutions, was made prior to 1898 or 1899.

JUDGE SPRINGER: What we are speaking about now is exclusively with reference to the examinations made by him and the other professors.

MR. JEFFRIES: When was that?

JUDGE SPRINGER: This was in 1899.

Q. (Last question repeated).

A. During April and the early part of May, 1899, I purchased the required number of outfits, and prepared them
7915 for the collectors to use in making their collections and arranged with the express companies for transportation of the samples from the various points that had been agreed upon, and reported to me by Professor Palmer and Professor Jordan, where the samples were to be taken. On the 19th of May, I sent a letter under the direction of Dr. Arthur R. Reynolds, the Director of Streams Examinations, to each of the collectors, in which the following was stated:

"According to arrangements that have been made by Professor Jordan and Palmer, you are to make collections of samples of water for the Chicago Sanitary District. These samples are to be collected at the particular places from where you have been instructed, on a certain day of each week. From each spot from which water is obtained three separate samples must be collected. As each sample is representd by a large bottle and a small one, six bottles must be filled with water. The shipping cases and outfits have been sent to you. The tags, seals and numbers you will find in one of three cans belonging to each sample. There is one press for the seals. This bears a number. This is your number as collector. The three samples are to be packed in the shipping case and sent to the three addresses indicated upon the shipping envelopes. The ship-
7916 ping envelope is to be fastened to neck of the large bottle, by the wire seal. The small bottles do not require shipping envelopes. The samples are to be numbered with the tin tags bearing numbers. Use the numbers in regular order. As there are six bottles from each locality there are six tags numbered alike and one of these is to be fastened by the seal to each bottle. In putting on the seals, pass the wire in and out through the holes in the cloth cover of the bottle. Read carefully the instructions on the cards that go in the shipping envelopes.

Q. You need not state how the bills were rendered for payment. That is immaterial as far as we are concerned. Was there any other circular sent after that to these collectors, if so, state when?

A. On the 31st of May, 1899, I sent the following letter to each of the collectors:

It is desired that you proceed in the following manner regarding the packing of the small sample bottles in the cans. When the bottle is placed in the sample can, the lid must be pressed firmly in place, so as to present water getting into it. The smaller can is then to be packed in ice in the large can. This can must be completely filled with ice. In the shipping case the packing paper goes around the can; the excelsior is to be stuffed into the 7917 corners and packed over the top of the can, filling up the top of the shipping case. The ice must be kept from melting as well as possible. We are about to send you one complete outfit for sample to use in case of accident to any of the regular bottles or cans that are in use. We are also sending you the thermometers for taking temperatures."

Q. Were any verbal instructions to be given to the takers of samples, and if so, by whom?

MR. JEFFRIES: I object to this witness stating about any verbal instructions being given to any sample takers unless such instructions were given by this witness.

JUDGE SPRINGER: I don't propose to put this in at this time; simply to lay the foundation.

MR. JEFFRIES: I don't suppose he would know whether there were or not.

(Question repeated).

MR. JEFFRIES: I object to the witness stating by whom they were given because that is no more competent than what the verbal instructions were themselves.

JUDGE SPRINGER: Well I withdraw the question then and will put another.

Q. Who selected the exact points in these various waters, at which samples were to be taken and employed the 7918 persons who were to take the samples?

A. Professor Palmer and Professor Jordan did that.

Q. Then personally you did not see any of these water takers or employ any of them?

A. I did see some of them at one time or another, but I didn't see them at the beginning of the investigation.

MR. JEFFRIES: The question was as to whether or not the witness saw any of them employed.

JUDGE SPRINGER: Yes.

A. Engaged?

Q. Yes?

A. No, I didn't see any of them engaged.

Q. That is what I mean, did you see any of them engaged in their work at any time?

A. Yes, I saw them several times engaged in their work along the river.

Q. What points did you yourself visit where water was being taken?

A. Well, I was at Bridgeport a number of times. I was at Lockport and Joliet.

Q. Did you yourself give any verbal instructions or other instructions than those you have mentioned, to the water takers at those places?

7919 A. I had a number of times, occasion to write to them, and wrote to them rather personal letters about their work, as special directions or instructions, to explain points more fully.

Q. Who selected them?

A. Professors Palmer and Jordan.

Q. Do you know the points in these various waters at which collections of samples were taken?

A. I know in a general way as to the points.

Q. Can you name them?

A. Illinois and Michigan canal—well, we had better put a heading to this. The samples were collected from the following points:

Illinois and Michigan canal at Bridgeport, 500 feet west of the pumping station.

Illinois and Michigan canal at Lockport.

Desplaines river at Lockport.

Illinois and Michigan canal north of Joliet, east bank, north of Jackson Street.

Illinois and Michigan canal south of Joliet, east bank of the railroad bridge.

Kankakee river at Wilmington.

Illinois river at Morris, at the bridge.

Fox river at Ottawa above the canal viaduct.

7920 Illinois river at Ottawa,

Illinois and Michigan canal at Ottawa,

Big Vermillion river at LaSalle at the bridge,

Little Vermillion river, once in four weeks,

Illinois river, LaSalle, at the wagon bridge,

Illinois river, Henry, at the dam.

Illinois river, Peoria, at Averyville bridge, at the Narrows,

Illinois river at Wesley City,

Illinois river at Pekin,

Illinois river at Havana, above the mouth of the Spoon river, in Quiver Lake.

Sangamon river at Chandlersville,

Illinois river at Beardstown,

Illinois river at Kampsville, above the dam,

Illinois river, Grafton, two miles above the mouth of the Illinois river,

Mississippi river, Grafton, above the mouth of the Illinois,

Mississippi river, Alton, Illinois, 100 feet from the east bank,

Mississippi river, Alton, east of the middle of the river.

7921 Mississippi river, Alton, Illinois, mid-stream,

Mississippi river, Alton, Illinois, west of the middle of the stream,

Mississippi river, Alton, Illinois, 100 feet from the west bank.

These five samples were taken opposite the new pumping station of the city waterworks at Alton.

Mississippi river, Mitchell, 400 yards from the Illinois shore.

Mississippi river at Mitchell, in the main channel.

Mississippi river, Mitchell, at the in-let tower,

Mississippi river, Mitchell, 400 feet from the Missouri shore.

These samples were taken opposite the St. Louis city pumping station.

Missouri river at West Alton, at the C. B. & Q. railway bridge.

Mississippi river at Jefferson Barracks, east bank, Mississippi river, Jefferson Barracks, east of the middle of the stream,

Mssissippi river, Jefferson Barracks, mid-stream,

Mississippi river, Jefferson Barracks, west of the middle of the stream,

7922 Mississippi river, Jefferson Barracks, west bank,

St. Louis city tap water, at St. Louis.

Q. Were the collectors of samples established at each of these places to which you have referred?

A. Yes.

Q. Did you know the names of those persons who were appointed by Professors Palmer and Jordan to take the samples of water at the various places here?

A. Yes sir, I had the names of the following individuals as collectors at the beginning of the investigation. There were a few changes afterwards that I cannot state just now.

Q. Well, you may state those names that were furnished you?

A. At Bridgeport J. E. Thomas. Do you want his title? The Assistant engineer at the pumping station.

Q. Yes, always give that. I want to ask you, was this in the Illinois and Michigan canal or in the drainage canal. There are the two at Bridgeport.

A. I know. This is the Illinois and Michigan canal.

Q. Well, just state that then.

A. Illinois and Michigan canal at Bridgeport, J. E. Thomas, Assistant engineer at the Bridgeport pumping station.

At Lockport from the canal and Desplaines river, P. W. O'Brien, the lock-keeper at Lockport.

Q. In the Illinois and Michigan canal? You must distinguish between those two canals. 7923

A. Yes.

Q. Well, proceed then.

A. At Joliet, in the canal, R. P. Eliott, Agent United States Express Company.

Ottawa from the Fox river and the canal, Dennis Foley.

Morris, Illinois river, J. W. Miller, and Miller had a man helping him named James Mack.

LaSalle, Big Vermillion river, Little Vermillion river and Illinois river, collector William Frazer.

Henry, Illinois river, James McCune.

Peoria, Averyville, sample, Illinois river, D. J. Forbes, Peoria Water works. He was connected with the Peoria water works.

Wesley city, Illinois river, D. H. Jansen, county surveyor.

Pekin, Illinois, Illinois river, collector D. H. Jansen.

Havana, Illinois river, H. J. Heberling,

Chandlerville, Sangamon river, E. O. Spink.

Beardstown, Illinois river, J. A. Carney.

Kampsville, Illinosi river, C. V. Brainard, Assistant United States Engineer.

7924 Grafton, Illinois river, Mississippi river above the mouth of the Illinois, and the Missouri river, B. F. Robinson, Grafton.

Alton, Illnois, five samples from the Mississippi river, George Brooks of Alton.

Mitchell, four samples, Henry Atkins of Mitchell.

West Alton, Missouri, James Matthews.

St. Louis, August Johnson.

Q. State doctor, whether any blanks were furnished these collectors upon which the results of their operations were to be entered?

A. Yes, the outfits were accompanied by a slip on which was recorded the number of the sample, the date and the time of collection, place of collection, by whom collected, the height of the water and the temperature of the water; direction of the wind, and the temperature of the air, and the rainfall to be noted at the time, for the time since the last samples were taken, and a place for remarks as to passing vessels or any other special circumstances.

Q. Was there anything printed on the back of this certificate?

A. On the back of this slip were printed the specific instructions for the collection of samples.

7925 Q. Will you state what the printed instructions on the back of these certificates were?

A. The instructions were as follows:

The outfit for obtaining water samples consists of two parts, the large gallon-bottle is for the chemical sample, and the

small four ounce bottle is for the bacterial sample. The large and the small bottle together constitute one sample or set. The two bottles must be filled at the same time and at the same place, and in the same general manner. They must then be placed in their respective compartments of the shipping cases, for transportation. In filling the bottles the stoppers must be taken out only when the spot from which water is to be taken is reached. The bottle is immersed with the stopper in place, about one foot below the surface and is filled, leaving about two or three inches air space. The large and the small bottles are then immediately sealed by placing the rubber cloth over the stopper and drawing the wire seal with the number of the sample, tight about the neck. The small bottle is to be placed in the smaller can, and the lid pressed down, it is then to be packed with ice within the large can. The card and the shipping envelope is then to be filled out and attached to the neck of the larger bottle. The bottles must not be filled until just
7926 before the time for delivery at the express office. As series of samples are to be sent to the different laboratories, all of the bottles should be filled at the same time at the same place, and the different sets placed together as described. The certificate of collection on the reverse side is to be filled out completely in every case.

Q. State in what condition were the samples received at your office in the city laboratory of Chicago, during this period?

A. The samples were received in very good condition as to their appearance, and the presence of the ice and the evidence that the instructions had been followed.

Q. Were these blank certificates filled up in the manner pointed out by you?

A. Yes, they were filled out. One or two of the collectors had some difficulty in getting temperatures, and they did not always fill in the temperature; that is the only point in which they failed.

Q. Who received the boxes containing the samples from the express office in your office?

A. Mr. Bisbee received all of the samples.

Q. What was done with the certificates or tags which accompanied these bottles?

A. The certificates were all saved and put up in serial
7927 order.

Q. By him?

A. Yes sir.

Q. After these samples were received in the Chicago laboratory, what was done with them?

A. Mr. Bisbee took his large bottles for the chemical analyses and delivered the small bottles for the bacteriological examinations to me, and I proceeded with my examination of the samples.

Q. Did he or you note on the certificate the time of the collection as it appeared upon the certificate and the time of making the examinations to which you have referred?

A. Mr. Bisbee filled out that part of the sheet.

Q. What method of physical or chemical examination was pursued in your office so far as these samples were concerned?

A. Well I left that to Mr. Bisbee and he made his chemical analyses.

Q. What method was pursued by you in making the bacterial examinations of those samples?

A. I made an examination for the numbers of bacteria of all kinds present in the samples by making Petre plate cultures on agar culture medium, and counting the number of colonies
developed, estimating then the number of bacteria present
7928 per cubic centimeter of water. Beyond this, an examination for bacteria of the colon-typhoid group was made. Preliminary cultivation of the water sample in glucose broth and separation of the bacteria therein present, with isolation of the colonies, and studied the specific characteristics presented by the cultures obtained from these colonies.

Q. What record, if any, did you make of those examinations?

A. I recorded the results of the examination on a record sheet.

Q. Did you record the height of the water or the temperature of the air from the cards which accompanied each sample, if those entries were upon such cards?

A. No, I didn't do that. Mr. Bisbee made those entries upon those cards.

Q. As to the bacterial examinations?

A. What?

Q. He made them as to all the samples?

A. As to all the samples?

Q. Did you make an entry upon any tables prepared by you of the presence or absence of the bacillus coli communis?

A. Yes.

Q. And did you make any entry of the number of bacteria per cubic centimeter?

A. Yes.

7929 Q. State how you designated on the tables prepared by you, the presence of the bacilli coli communis?

A. I designated it by a plus sign.

Q. A cross?

A. Yes.

Q. And where there is no designation, what does that mean?

A. Where there is no designation at all?

Q. Yes.

A. That for some reason or other the examination was not completed or fully carried out.

Q. And perhaps there was no ascertainment at all. You did not reach a conclusion I mean, as to whether they were present or not?

A. No, the fact that there was no examination upon which to draw a conclusion in that particular case.

Q. Did it mean that you looked for them and did not find them or that your examination was insufficient to find them?

A. In that case the examination was insufficient or lost or destroyed in some way. Where they were not found the record was made by indicating a minus sign, a straight dash.

Q. Professor, I hand you certain tables numbered from 159 to 196 inclusive, entitled "Streams Examinations, Sanitary District of Chicago, Sanitary Water Analyses, Parts Per
7930 Million; Source of water" indicating at each place in that table where the source was, and designated as a report of Adolph Gehrmann, and D. B. Bisbee, Municipal Laboratory, Chicago, Illinois. Will you please examine these tables and state whether or not these are the tables that were prepared by

you and Mr. Bisbee, as chemist in the city laboratory of Chicago, at the times indicated on each of these tables, as the results of chemical analyses and bacteriological examinations of the samples of water taken at various places during the time indicated, in the waters indicated by you in your examination up to this time?

A. These tables that I present are the tables that are prepared in connection with Mr. Bisbee,—the record of work on the samples that we received from the collectors at the points as stated before.

Q. Were these tables made as to both analyses, and examinations under your direction and supervision?

A. Yes; that is, we worked together on them.

Q. And you were in charge of the work?

A. Yes, in a general way.

Q. State whether these tables then so far as the column indicating presence or absence of the coli and that indicating the number of bacteria per cubic centimeter were made by you, entered by you and whether they are the correct ascertainments of the examinations you made of said waters at the times indicated and the places indicated? 7931

A. The column here designated presence of bacilli coli communis, contains the record of the results of the determinations that I made on various samples received from the localities, as stated at the head of the table.

Q. We will take as a sample of all of them, table No. 159. It is stated upon that table that the sample was taken July 3rd and examined July 3rd of the year 1899, and that the presence or absence of the bacilli coli communis is indicated by a cross. Explain what that means.

A. This means that on the 3rd of July we examined a sample collected on the 3rd of July from the Illinois and Michigan Canal at Bridgeport, and found the bacillus coli present.

Q. In the sample collected on the 14th of August and examined on that day, what is indicated on that table?

A. The indicaion as regards the sample of water examined August 14th, collected August 14th from the Illinois and Michigan Canal was that the examination was not completed and no definite record was made.

Q. As to the colon?

7932 A. Yes.

MR. JEFFRIES: In other words, there may have been colon and there may not have been, and that determination was not made because the sample was either lost or destroyed, or something of that kind?

A. It was mainly because I was doing other work and did not finish it, or could not finish it.

Q. In other words, no determination of that particular organism was made?

A. Yes.

Q. JUDGE SPRINGER: Now doctor, you may state whether similar entries were made on those tables with regard to the presence or absence of coli communis in all of the tables that you have in your hand?

A. Yes sir.

Q. And that where they appear there to be understood as indicating the results which you have explained as to this table, the same sign for the same meaning, in other words?

A. There is in one or two places you will find, as for instance on the Lockport table No. 160 on October 11, a question mark,—an interrogation point.

Q. What does that mean?

7933 A. That means that there was doubt as to the result of the examination one way or the other, as to the presence of the colon bacillus. I believe there are only one or two such points, or only one I believe.

Q. Well, in other words, with that explanation then, the same method was pursued in making up each of the tables to which I have called your attention?

A. Yes sir.

Q. Now I call your attention to the last column on the right hand side of that table, which is headed "Number of bacteria per cubic centimeter." State what that column is intended to convey?

A. This column which is marked "Number of bacteria per cubic centimeter" records the number of bacteria found by an average of the portions of the sample examined, as estimated present per cubic centimeter.

Q. Did you make all those bacterial examinations and ascertainments of results by the usual methods employed by bacteriologists for making such counts?

A. I made them by the agreed methods, as I have already partially stated.

Q. What were those?

A. Agar plates of aliquot portions of the samples, counting the number of colonies, estimating the number of bacteria present. 7934

Q. State whether that system has been used by bacteriologists generally for the purpose of making such ascertainments?

A. Yes, it is the standard method.

Q. State whether or not then in the tables to which I have called your attention the column on the right hand side of the page, the last column, contains a true statement of the result of such counts of the samples taken and examined, and the dates indicated, and the places indicated on that table?

A. That is a true record of the results of the examinations made by me.

Q. And those entries were made by you as the results of your examinations?

A. Yes sir.

Q. State whether or not the subsequent tables to the end of the number I have given you contain similar results of your bacterial examinations?

A. You mean beyond 159?

Q. Yes?

A. The tables 159 to 196 inclusive contain the record of my examinations as to the numbers of bacteria present in these samples of water.

7935 Q. Then these tables, the numbers of which you have given, so far as the two columns about which we have been speaking are concerned, were made by you, and are the results of examinations made by you?

A. Yes sir.

Q. And are known to you to be correct examinations?

A. Yes sir.

Q. Doctor, you will now please read each of the tables to which your attention has been called, beginning with tables 159 and ending with table 196.

MR. JEFFRIES: To the reading of which said tables, complainant objects for the reason that an adequate number of samples was not examined to enable a sanitarian to express an opinion or draw any conclusions thereform as to the sanitary condition of the water in the river at the points where the samples were taken, and for the further reason that examinations were made and samples collected without reference to flood seasons or low water seasons, without reference to low temperature or high temperature and without reference to the changing conditions of the water, and the variations of the water and
7936 the weather. I object to the reading of the tables into the record for the further reason that certain analyses bacteriological and chemical have been made or purport to have been made by said tables, of the waters of the tributaries of the Illinois river, such examinations being immaterial and having no bearing upon the issues involved in this case, and for the further reason that even if they should under any circumstances be considered evidence of the remotest character or of any character whatever, a sufficient number was not taken from these tributaries to determine the sanitary condition of the water in the tributaries. I object for the further reason that the samples so taken from the tributaries were not taken with reference to the sources of pollution from the water-shed of the tributaries, and were not taken with reference to the changing conditions of the tributaries, with reference to flood season, low water season, winter season and summer season. I object to the reading of the tables into the record for the further reason that they do not furnish proof of any character as to the disappearance of pathogenic organisms passing from the city of Chicago down the Illinois river.

I object to the introduction of the tables for the further reason that the life and conduct of disease producing germs in running streams has never been determined, and that
7937 all bacteriologists practically agree that such a determination has never been made and cannot be made. That they will live in the laboratory under various conditions from five to 90 days and possibly longer, and that from bacteriological

analogy, they will live much longer in a running stream, where they are able to leave, swim or move from the sources of danger, and where all sources of danger and destruction to them is continually being swept away by the water; that they may live much longer in the running stream than in the laboratory experiment. And I object therefore to the reading of the tables into the record for the reason that the only question so far as the defense is concerned in this case is that as to whether or not the life time limit of the disease producing germs has expired before the water from the Chicago river passing through the drainage canal, has reached the State of Missouri. I also object for the further reason that the defense has proven the presence of pathogenic germs of spore forming character, which lived for months, and not in a running stream, and that as to those the chemical analyses are of no importance as to showing the disappearance of such germs from the Illinois river.

I object to the reading of the tables into the record for the further reason that the proper foundation has not been
7938 laid for their introduction, no evidence as to the proper
precautions having been 'given with reference to the increase and growth of the bacteria in the samples of water after they were taken, prior to the experiment, or the analysis and for the further reason that the witness has not stated the character and amount of solid organic matter added to the samples by way of his experiment, which would produce an added and increased number of bacteria in the samples, and therefore change the bacteria conduct in the operation of the water so analyzed.

I object to the reading of the tables into the record for the reason that they are not the tables made by the witness when the experiments were made, and could not have been the original tables for the reason that the tables now being read into evidence are printed, while the originals must necessarily have been made with a pencil or pen and ink.

JUDGE SPRINGER: Counsel for defendants states that this objection ought not to be entered of record in this case for the reason that it is in most respects merely a comment upon the weight of the evidence and not a proper objection as to its admissibility, and for the further reason that counsel has recited in his objection a number of alleged facts which ought not to go into this record except as the testimony of a witness 7939 and are merely his conclusions as to the weight of the testimony that has heretofore been introduced in evidence, and further that the part of the objection which states that there is no evidence as to the height of the water in the channel is incorrect for the reason that there is a column in these tables showing the height of the water, the temperature of the water and the temperature of the air at each of the places where the respective samples were taken; also a table showing the residue on evaporation or the total solids, and that these matters will be referred to by subsequent witnesses who made up that part of the table, this witness merely being confined to the two columns in this table which he prepared himself, and further that the statement that these tables are not the highest evidence is merely an opinion of counsel and therefore improper as an objection. That the witness has stated in his examination that this table was made up by him, of the results of examinations of the water made by him and that it is a correct statement of the result of those examinations. Now he can make that statement as the person who made the examination, without reference to a book of any kind. He can make it from his memory, or he can refresh his memory from any table that he has got before him.

MR. TODD: For the information of myself, one of the counsel in this case, I would like to request counsel for 7940 complainant to state if possible, the number of samples that it would be necessary to take in order to render this objection made by him void if the same be good, and also whether there has been established in this case or out of it, any established rules requiring any certain number of samples to be taken in order to make the testimony admissible. The reason for this request is based on the fact that witnesses on complainant's side of the case drew conclusions from as many as one sample taken, and in some cases from as many as two, and as many as three in number, and others drew conclusions from a greater number of samples, so that if counsel knows of any established rule that would apply against the defense in this case, to show that his objection as stated is a good legal objection, and for the information of counsel and for the illumination of the record upon that point, I would like to ask counsel to state what that number is, and this request is made with the greatest deference and respect to counsel's knowledge on the subject.

MR. JEFFRIES: I suggest to the Court that I don't object to counsel as contained in Judge Springer's dictation, commenting upon the evidence and what it shows, but I do suggest to the Court that the defendants' own witnesses have shown that no determination of the longevity of disease-producing germs and spores in running water can be determined
7941 from a laboratory experiment or from laboratory experiments, although a large number of the examinations may be made. For the information of Mr. Todd I will say that upon the admission of the deposit of disease producing germs into the sewage of Chicago river and the canal, and upon the evidence of the bacteriologists introduced on the part of the defendants, and taking into consideration the evidence thus far introduced by the defendants, that the typhoid bacilli and various other forms of disease producing germs, anthrax and tetanus spores, which have been found in the waters of the Illinois river since the opening of the canal live for a period limited only by years, and that the typhoid and other disease producing bacilli lived from five to ninety days under various conditions in water taken from running streams, and that the bacteriological analogy applied thereto, and as testified to by witnesses for the defense, that they would live much longer in running streams it remains for the defense to purge the river of disease producing germs, deposited into it by the city of Chicago.

MR. TODD: In view of the fact that this objection is made to the very first tables introduced in evidence by the defendants, on the ground that the number of samples were not sufficient to predicate a judgment on, and to other subsequent tables, counsel's explanation may be sufficiently understood by the
7942 superior wisdom of the Court, but he failed entirely to give me the number of samples necessary, for an expert to predicate a judgment on as modestly requested by myself.

MR. JEFFRIES: I suggest to counsel that if the samples of water were examined at given points as shown by the testimony of defendant's witnesses during the entire year, that that would not be evidence, and the result of these experiments would not be evidence of the absence, or would not show the absence and be proof of the absence of pathogenic germs. Now I object further to the reading of the tables into the record for the reason that on their face they show nothing that would prove or tend to prove that the typhoid bacilli, anthrax, tetanus, cholera vibrio and various other disease producing germs will disappear or have disappeared from the Illinois river after being deposited into the sewers of Chicago and thence into the Chicago river and the drainage canal by the time the water from the Illinois river reaches the shores of the State of Missouri on the river.

MR. TODD: I still insist that counsel has given his opinion as a standard to govern a scientific investigation such as this and that was not what I called for, because his opinion 7943 is rated by the evidence that was put in by the side of the case that he represents, but I ask for any accepted standard of numbers of analyses and not for an opinion.

MR. JEFFRIES: I take it for granted that a reference upon this proposition will satisfy counsel and in this connection I refer him to the testimony of Professor Zeit, who is a witness of the Sanitary District of Chicago and the State of Illinois in this case, and who has furnished me my information and reason stated in the objection.

MR. TODD: In reply will state that this objection was made heretofore and this request made before Professor Zeit went on the stand.

JUDGE SPRINGER: If the Court please, I move to eliminate all of these objections that have been made since these tables were offered in evidence for the reason that they are principally arguments addressed to the court in reference to the weight of testimony and conclusions of counsel as to what testimony has established in this case proves, and that all such matters must be addressed to the Court either in oral arguments, or in briefs, which they will submit to the Court when the case is called for hearing.

MR. JEFFRIES: I will suggest to counsel that I have never yet known of a case where the Court has sustained 7944 a motion to strike out objections to evidence.

MR. TODD: I would in reply to counsel state that that counsel has set the precedent in this hearing of moving to strike out objections to testimony.

JUDGE SPRINGER: The witness will now please read the tables to which I have referred, into the record.

MR. JEFFRIES: To the reading of which said tables into the record, I renew my objection.

THE WITNESS: The tables are as follows:

ABLE 159.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

SOURCE OF WATER—ILLINOIS AND MICHIGAN CANAL, BRIDGEPORT.

Report of ADOLPH GEHRMANN,
D. B. BISBEE,

APPEARANCE—H., Heavy. VH., Very Heavy. VVH., Very, Very Heavy. S., Slight. VS., Very Slight. VVS., Very, Very Slight. M., Medium.

7982 Adjourned until 2:00 P. M., same day, Friday, October 9, 1903.

2:00 P. M., October 9th, 1903.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ADOLPH GEHRMANN,

resumed the stand for further direct-examination by Judge Springer, and testified as follows:

Q. At the time of the noon adjournment, you had read in evidence the tables about which you had testified, beginning with No. 159 and concluding with No. 196. Please state whether or not these tables so read in evidence by you contain a correct statement of the results which you obtained by the bacteriological examinations which you made of the waters referred to in those tables, and also in your ascertainment of the presence or absence of the bacilli coli communis?

A. They contain a correct statement of the results of the findings.

Q. I call your attention to the first table. Please state from what point table No. 159 purports to have received the samples of water?

A. This table of analysis shows the results of the examination of samples from the Illinois and Michigan canal at Bridgeport. 7983

Q. And the next table, No. 160, where were the waters taken from upon which that table is based?

A. This table, table 160, is a record of the results of examinations of the waters of the Illinois and Michigan Canal at Lockport, Illinois.

Q. I desire to call your attention to table 165, and ask you at what point the samples of water were taken upon which that table is based?

MR. JEFFRIES: Now I object to the witness testifying from the tables or to anything in connection with the tables for the reason mentioned in my objection to the reading of the tables into the record.

A. This table, table No. 165, is a record of the examinations made of the waters of the Illinois river at Morris, Illinois.

Q. Now I will ask you to turn to table No. 171 and state at what point in the Illinois river were the samples taken, the results of which are stated in that table?

A. This table, table 171, contains results of the examinations of the water of the Illinois river at Henry, Illinois.

7984 Q. Now I call your attention to the table numbered 172, from what point was the water taken upon which that table is based?

A. This table, table 172 contains the results of the examination of the waters of the Illinois river at Averyville.

Q. Well, state if all the examinations which you have referred to in all these questions, mean bacterial examinations?

A. Yes.

Q. Please cast your eyes over the last column at the right hand,—the right hand column of table No. 159, which shows the results obtained from examinations of waters, taken from the Illinois and Michigan Canal at Bridgeport. Did you make any averages of the total findings for the various dates mentioned during that period?

A. No, I have no averages for these figures.

Q. What dates do those samples cover,—the examinations?

A. The samples in table 159 are for a period from July 3rd to November 27th, 1899, and the samples in table 172 are for a period from July 3rd to November 28th, 1899.

Q. Substantially the same period?

A. The same period practically.

Q. Now what do you find upon the column which is headed "Number of bacteria per cubic centimeter" on table 159, Bridgeport, as to the numbers?

7985 MR. JEFFRIES: I object to the question for the reason that the witness is called upon to give comparative statements as to conditions existing prior to the opening of the canal and those conditions representing merely the conditions that existed in the Chicago river prior to the opening of the canal, and therefore are not comparable with conditions existing since the opening of the drainage canal.

JUDGE SPRINGER: They are comparable in the opinion of counsel for defendants for the purpose of establishing the conditions previously existing, and those which existed subsequently to the turning in of the waters coming from the drainage canal.

MR. JEFFRIES: I submit that it is not a question as to whether the conditions are the same or different now from what they were prior to the opening of the canal, but the question involved in this case is the disease producing germs discharged into the canal by the city of Chicago by means of the drainage canal constructed on the part of the sanitary district, being removed before the waters reach the Missouri shore.

(Question repeated).

Q. JUDGE SPRINGER: What is the least number stated there in that column?

A. Is this another question?

7986 Q. This is the same question. I asked you to look at it. What is the lowest number stated?

MR. JEFFRIES: At which point, Judge?

JUDGE SPRINGER: At Bridgeport,—table 159.

A. The lowest figure as to the bacteria per cubic centimeter in the analyses made of the waters of the Illinois and Michigan canal at Bridgeport was 81,350 bacteria per cubic centimeter.

Q. On what date is that?

A. That was on July 17th, 1899.

Q. What was the largest number found?

A. The largest count was made from the sample collected November 27th, 1899.

Q. What was that?

A. 8,425,000.

Q. State whether the other ascertainments given in that column are within the limits to which you have referred?

A. Yes, they are within the limits.

Q. You stated that you have made no averages. What is your opinion as to what the average would be from this column?

A. Well the average number of bacteria would be—

Q. For the period?

A. For the period would be somewhere in the hundred thousands column.

7987 Q. Now take the corresponding column for Averyville in table 172, what is the lowest ascertainment there?

A. The least number of bacteria found in any of the examinations of the Illinois river water at Averyville, is 7,350 bacteria per cubic centimeter.

Q. What is the largest you found?

A. The largest number of bacteria found in any of these samples was 50,000 bacteria per cubic centimeter.

Q. From an examination of these two tables, and the results stated therein as to the bacterial count at Bridgeport, and the bacterial count at Averyville, what conclusions do you draw, as a bacteriologist?

MR. JEFFRIES: I object for the reason that the witness is called upon to draw conclusions upon conditions that existed prior to the opening of the canal and which do not exist now, so that any conclusions that may be drawn by this witness or any other witness upon such prior existing conditions, is not relative, material or competent in this case, because the conditions by reason of the added volume of water and by reason of the construction of the canal and by reason of the hastening of the disease producing germs away from Chicago have materially changed.

Q. (Question repeated).

7988 A. From an examination of these two tables, and the figures contained therein, I should conclude that in the first place there was a difference of from ten to twenty per cent. in the number of the bacteria present, it being less for the samples at Averyville than for those at Bridgeport, and in some instances a difference of 100 per cent., in favor of the samples at Averyville. I should further conclude that the samples collected at Averyville showed a much greater bacterial purity than those collected at Bridgeport.

Q. Please make a similar comparison with the waters mentioned in table 160, of samples collected from the Illinois and Michigan Canal at Lockport, and those that were mentioned on page 172 at Averyville. Now state your conclusions as a bacteriologist?

A. From an examination of the samples collected from the Illinois and Michigan canal at Lockport and those collected from the Illinois river at Averyville, I should conclude in the first place that there were from ten to twenty per cent. less numbers of bacteria in the Illinois river waters at Averyville and in some

instances a difference of 100 per cent., in favor of the samples from the Illinois river at Averyville, and should conclude that the water in the Illinois river at Averyville shows a much greater bacterial purity than the waters of the Illinois
7989 and Michigan Canal at Lockport.

Q. I call your attention to table No. 165, showing results of examinations made of waters taken from the Illinois river at Morris, Illinois. Please state what in your opinion is disclosed by bacterial count of the samples of water indicated, at Morris, Illinois, as compared with those at Bridgeport in the Illinois and Michigan canal and also as compared with those at Averyville, contained in table 172?

A. Comparing the results of my examinations of the waters of the Illinois and Michigan Canal at Bridgeport, the waters of the Illinois river at Morris, the waters of the Illinois river at Averyville, I should conclude in the first place that the numbers of bacteria present are not materially different in the waters of the Illinois and Michigan canal at Bridgeport, and the Illinois river at Morris, and that the waters of the Illinois river at Averyville contain from ten to twenty per cent. of the number found at the other two points, and in some instances one per cent. of the numbers found at the other two points, more particularly at Bridgeport, and that the bacterial condition of the water represented by these tables, shows that the water of the Illinois river at Averyville is of greater bacterial purity than the water of the Illinois river at Morris or the waters of
7990 the Illinois and Michigan Canal at Bridgeport.

Q. I call your attention to table 171, which states the results of bacterial examinations of water taken from the Illinois river at Henry. Please state what is indicated by the differences here disclosed as to the number of bacteria found at this place and at Morris and at Averyville?

A. A comparison of the results of the examination of the samples of the water in the Illinois river at Morris, Illinois, the Illinois river at Henry, Illinois, and the Illinois river at Averyville, show from the numbers of bacteria present, that there is not a material difference between samples collected at Henry, Illinois and Averyville, except in two instances,—August 8th and September 30th, when they were much higher in the Illinois river at Henry. The bacterial counts at these two points are ten to twenty per cent of those as found at Morris, and show that the water at Henry and at Averyville is of greater bacterial purity than the water of the Illinois river at Morris.'

Q. Please examine table No. 164, which shows the results of your examinations of the water taken from the Kankakee river at Wilmington and also state what relation they bear numerically to those found in the Illinois river at Averyville?

A. The bacterial counts of the waters of the Kankakee
7991 river at Wilmington, Illinois and of the Illinois river at
Averyville, show only slight differences. In some instances they are in favor of the Illinois river and other instances they are in favor of the Kankakee river. The samples are taken about the same time, or near the same time.

Q. From an examination of these two tables, what do you conclude as to their relative significance from a bacterial standpoint?

A. From a bacterial examination or standpoint I should conclude that there was no material difference in these two waters as to their bacterial purity.

MR. JEFFRIES: I move to strike out the conclusions of the witness drawn in reference to the bacterial condition of the water in the tributaries of the Illinois river, and object to the witness testifying in reference thereto, for the reason that it is incompetent, immaterial and irrelevant.

Q. JUDGE SPRINGER: Assuming, professor, that the Kankakee river above the mouth of the Desplaines river is merely an upper portion of the Illinois river, differing only in name, from the lower reaches, and assuming that the condition of the water contained in the Kankakee river before its confluence with the Desplaines river to be as stated in your testimony heretofore, what is your opinion as a bacteriologist,
from an examination of the two tables to which your at-
7992 tention has been called, as to whether or not the Illinois
river at Averyville has reached a condition bacterially substantially the same as that which it had before the waters of the Desplaines river and the Chicago drainage canal and the Illinois and Michigan canal were emptied into it?

MR. JEFFRIES: I object to the question first because the condition of the Kankakee river is not in controversy in this suit.

I object to the question for the further reason that it is not assumed in the question that the same amount of sewage material is deposited in the Kankakee, as is deposited in the Desplaines, the canal and the Illinois river.

I object to the question for the further reason that the assumptions are based upon the bacterial changes in the waters of the Illinois river without reference to the reduction of pathogenic germs.

I object to the question for the further reason that when a river has been subjected to sewage pollution, it is not a question as to the number of bacteria alone that may be found in that river, but the character of the bacteria, with reference to whether they be pathogenic or non-pathogenic, and I object to the question therefore for the further reason that there is nothing within the science of bacteriology, outside of the lab-
7993 oratory or in the laboratory that will enable a bacteriolo-
gist from his examinations alone, to determine from mere counts of bacteria the presence or non-presence of disease producing germs in the water of the river.

A. From an examination of the bacterial counts as made of the samples of water from the Kankakee river at Wilmington, and from the Illinois river at Averyville, I should conclude that the examination showed very much the same conditions as regards bacterial purity, the numbers in the majority of instances being not very different.

Q. Then if we assume that there is such a thing in the Illinois river as a zone of bacterial purification where in your opinion as a bacteriologist, is this zone to be found in the Illinois river?

MR. JEFFRIES: I object to the question for the reason that it is impossible to determine the zone of bacterial purification in any stream after it has been once polluted by sewage.

JUDGE SPRINGER: By bacterial zone I mean a place in the river where it resumes bacterially the conditions which were observed in the water before any alleged pollution was received in the river.

MR. JEFFRIES: Modify my objection so that it may
7994 read as follows:

I object to the question for the reason that there is nothing in the science of bacteriology that will enable one to determine the exact zone of purification of a running stream for sanitary and hygienic purposes, after it has been polluted by the sewage of a city, unless the time of life or longevity of disease producing germs is taken into consideration in connection with the flow of the stream.

Q. (Question repeated).

A. In reply to this question I can say that from the examination of the samples and the number of bacteria found, that there is a point at about Averyville where the condition as to the number of bacteria exists about equal to that of the tributaries of the river, and that the waters here show the least numbers of bacteria in the course of the river to the point at which they increase next below. I should therefore say that a degree of purification had taken place at about the location of Averyville in the river.

Q. So far professor, as the number of bacteria found in a given quantity of water indicates bacterial purity or impurity, what is your opinion as to whether a comparison of the counts in the Kankakee river to which your attention has been
7995 called, and those at Averyville, indicate any effect upon
those numbers which may have been created by the incoming at the mouth of the Desplaines river of any sewage from the city of Chicago.

MR. JEFFRIES: I object to that question for the same reasons contained in the previous objection.

A. My opinion would be from the bacterial count, that there was no particular difference in the bacterial purity of the waters at these two points, and nothing that would indicate to us to what amount pollution had been applied between these points or near these points.

Q. I call your attention now to the table numbered 173, which shows the result of your bacterial examinations of waters taken from a place below Peoria called Wesley City, and also table 174 which shows the results of your bacterial examinations of waters taken from a place below Pekin, Illinois. State what those two tables disclose to you as to bacterial counts, compared with the table in reference to Averyville about which you have already testified?

A. The results of the examinations of Illinois river water at Wesley City, and at Pekin showed very much the same condition. There is a wide variation between the counts made at different times, some being as high as two or three million.

Q. Six million at Wesley City?

7996 A. Well, several million, and again others as low as 10,-
000. In comparison, the examination of the waters of the Illinois river at Averyville shows in general a much smaller number of bacteria present, not in any instance having been over tens of thousands, and would indicate to me that the water of the Illinois river at Averyville is of greater bacterial purity than the water of the Illinois river at Wesley City, or at Pekin.

Q. From the difference in these results which is apparent, to what do you attribute the increased bacterial count at Wesley City and Pekin as compared with that at Averyville, if you know?

A. I attribute that to increased pollution of the river.

Q. Do you know from your knowledge, where that increased pollution comes from?

A. I have seen it coming from the city of Peoria and in that neighborhood.

Q. If you should compare, professor, the tables in reference to Wesley City and Pekin with those in reference to Bridgeport and Lockport, state whether there is any similarity or not as apparent from these counts as to the bacterial condition of the waters at the respective places?

A. A comparison of the bacterial counts of the Illinois and
Michigan canal at Lockport and the Illinois river at
7997 Wesley City and at Pekin show approximately the same
amount of bacterial impurity as to numbers, except that at Wesley City and at Pekin the individual figures are subject to slightly more variation.

Q. I now call your attention to table 179, which shows the result of the bacterial examination of the waters taken from the Illinois river at Grafton, Illinois, if you compare that table with the tables in reference to Wesley City and Pekin, what is indicated as to the bacterial changes if any, which have taken place?

A. The results of the examination of the Illinois river water at Wesley City and Pekin as compared with those at Grafton, in the Illinois river, show that at Grafton there are from ten to twenty per cent of the bacteria present as shown in the samples from Wesley City, and Pekin, and in some instances, one per cent of the bacteria that are present at Pekin and Wesley City.

Q. What conclusion do you draw from this as a bacteriologist?

A. I should conclude from this that the waters of the Illinois river at Grafton show a much greater bacterial purity than those at Wesley City and at Pekin.

Q. If you compared the waters of the Illinois river as disclosed by table 179 at Grafton, with the waters of the
7998 Illinois river at Averyville, as disclosed in table 172, what conclusion do you draw so far as these counts are concerned, as to the relative bacterial purity or impurity of the water?

A. I should conclude that the bacterial purity of the water or its condition, was about the same.

Q. What inference do you draw then as a bacteriologist, and considered from a bacterial standpoint, as to whether the pollution which entered the Illinois river at Peoria has or has not disappeared at Grafton?

A. I should conclude from the bacterial count made on samples of the water of the Illinois river at Wesley City, and Pekin, and at Grafton, that as far as the bacterial purity is concerned, the river had changed to the condition that we find it in from examination of the samples taken at Averyville, above the city of Peoria.

Q. I call your attention professor to table No. 180, which purports to contain the results of examinations of water made of the Mississippi at Grafton, and I call your attention to the bacterial counts found upon that table and ask you to compare those counts with those of the waters of the Illinois river at Grafton found in table 179, and state what those tables disclose as far as those two places are concerned?

7999 MR. JEFFRIES: I object to the question for the reason that the condition of the Mississippi river above Grafton is not at issue in this case and for the same reasons stated in the previous objections with reference to not being a question of the number of bacterial counts contained in the river, but a question as to whether or not disease producing germs from Chicago are not of such a character as to produce fatal effects upon the citizens of the State of Missouri.

Q. (Question repeated). In reference to the bacterial purity or impurity of the two streams?

A. The results of bacterial count of waters—of samples taken from the waters—of the Illinois river at Grafton and those taken from the Mississippi river at Grafton show no material difference and I should conclude from this that the bacterial condition of the two rivers is approximately the same, from the numbers of bacteria present.

Q. I call your attention professor, to table No. 190, which contains the results of your examination of the waters of the Missouri river at Fort Bellefontaine, or West Alton, Missouri, and ask you to state whether or not that point is above the mouth of the Missouri river and where that river has received no waters from the Mississippi river as far as you know?

8000 A. As far as I know it is above that point.

Q. Please examine the bacterial count on that table and compare it with the bacterial count of table 171, which contains the results of your examinations of the Illinois river water at Grafton and state what is disclosed by these respective tables as to the relative bacterial purity or impurity of the waters of the two streams at the respective points indicated?

MR. JEFFRIES: I object to any testimony with reference to the bacterial purity or impurity of the Missouri river, because that question is not in controversy in this case, and for the same reasons stated in the previous objections upon this subject and in reference to conclusions drawn from these tables.

A. The results of the bacterial counts made on the Illinois river at Grafton, and the Missouri river water from Fort Bellefontaine, show that there is no great difference as to the numbers of bacteria from these two points. I should therefore conclude that the bacterial purity or impurity of the two streams is about the same.

Q. I call your attention professor, to tables Nos. 186, 187, 188 and 189, which show bacterial counts of water taken from the Mississippi river at the chain of rocks above the city of St. Louis, where the city of St. Louis takes its water supply?

8001

A. Bacterial counts made of the samples of water taken from the Mississippi above the station at the chain of rocks, the pumping station of the St. Louis waterworks, all show practically the same bacterial counts, and I should conclude that the bacterial purity or impurity of the water at this point is about the same.

Q. I call your attention to the fact that table 186 shows the examination of samples taken from the Mississippi river 400 yards from the Illinois shore at the chain of rocks, and that table 189, contains the results of your examination of samples taken at the same place, 400 feet from the Missouri shore; what difference do you discover if any, in these bacterial counts at these two places?

A. There is no material difference. The bacterial counts from samples 400 yards from the Illinois shore, compare with those 400 feet from the Missouri shore, at the chain of rocks.

Q. I desire you to look at table 195, which shows the results of examinations of water taken from the Mississippi river 100 yards from the Missouri shore, and Jefferson Barracks, Missouri, which is a point on the Mississippi river about eight miles below the Eads Bridge of St. Louis, and about eighteen
miles below the St. Louis intake. That above Jefferson
8002 Barracks, the greater portion of the sewage of St. Louis
is discharged into the Mississippi river. Please state what the bacterial count for these places indicates as compared with the count in table No. 188, which is the result of your examinations of the waters taken from the chain of rocks inlet tower of the St. Louis waterworks?

MR. JEFFRIES: I object to the question because it is incompetent, irrelevant and immaterial.

A. Examination of the result of samples of Mississippi river water taken at the chain of rocks, as shown in table 188, compared with the examination of samples of the Mississippi river water taken at Jefferson Barracks, 100 yards from the Missouri shore, shown in table 195, show no material differences as to the number of bacteria present, and I should conclude that the waters at these particular points show approximately the same bacterial purity or impurity.

Q. State professor, in the examinations which you made of the waters of the Illinois and Michigan canal and of the Illinois river whether you made any effort to ascertain the presence of pathogenic germs?

A. I made an examination for the colon bacillus and the typhoid bacillus.

Q. Did you make any examinations to determine the
8003 presence of any other pathogenic germs?

A. No sir.

Q. State whether the results of your examinations for the presence of the bacillus coli communis are correctly stated in the tables which you have read in evidence?

A. They are.

Q. As heretofore explained by you?

A. Yes sir.

Q. State whether you discovered in any of these examinations, the presence of the typhoid bacillus?

A. No, I did not.

Q. State whether you discovered in any of these waters, or in any of the waters you examined during the time you were director of this laboratory, the presence of the bacillus prodigiosus?

A. You mean in waters?

Q. Yes, in any of the waters you examined coming from Lake Michigan, the Illinois and Michigan Canal or the drainage canal?

A. I cannot say that I found it in waters. I can say however, that I have found it during the examination of waters.

Q. That is what I mean, your examination of waters.
8004 Where did it come from in your opinion?

A. My opinion is that it was an accidental entrance upon the culture plate.

Q. What in your opinion caused that entrance?

A. In some way through the making of the plates, the preparation of the plates, that it arrived on the plates as a contamination approximately.

Q. Did such ascertainment or discovery indicate there were in any of these waters in the vicinity of Chicago the bacillus prodigiosus?

A. I cannot say positively that it indicated that.

MR. JEFFRIES: I object to the question as leading.

Q. JUDGE SPRINGER: What did your tests indicate?

A. They indicated to me that the bacillus prodigiosus is occasionally present in this vicinity, and can be found by exposing material suitable for it to grow, in various places.

Q. I believe you stated, professor, that you made no tests in reference to determining the presence of any other pathogenic germ than the bacillus coli communis and the typhoid bacillus, is that correct?

A. That is correct, yes sir.

Q. If there had been any other germs which are denominated pathogenic, you wouldn't have discovered them as you made no effort to do so? 8005

A. In regard to that point of course, if there had been large numbers of any particular kind, I would have found them. They were evidently not numerous enough to show in the procedures that we used for the isolation of the colon and typhoid and intermediate organisms.

Q. Are the bacterial examinations which you made of waters for the purpose of ascertaining the presence of bacteria generally of such a nature as to disclose the presence of any kind of bacteria which could be in the particular sample of water which you are examining if the particular bacillus is of sufficient size to be discovered by a microscope?

A. Yes, examinations for bacterial counts will give organisms that will grow under the conditions in which the colonies are made, and some bacteria of course will not be developed. We will have to admit that they are lost in the examination. If certain other varieties are present in large enough numbers, they will appear in the examination as a definite part of the examination, so that in reply to this question I cannot say that we would have positively isolated the other bacteria present.

Q. What did you state was the method employed by you 8006 for the purpose of ascertaining, the presence of bacteria in the waters which you examined?

A. Do I understand now the count of bacteria?

Q. Yes.

A. It is what is known as the Petri plate culture method.

Q. What kind of culture or material do you use for the purpose of developing bacteria?

A. In this case we used the agar culture media.

Q. What is agar?

A. Agar is a vegetable substance in the nature of starch found in some plants, and extracted by boiling, seaweed plants, extracted by boiling and purified.

Q. It is a substance then which bacteriologists have found suitable for the purposes of making these tests?

A. Yes sir, it is suitable for the solidifying of culture media, so prepared or containing such material, suitable for the growth of bacteria.

Q. Please state professor, what your duties were at the time you were connected with the Health Department of this city?

A. My general duties were as superintendent of the laboratory to arrange the work and see that it was carried on properly, in the examination of samples of the city water and milk and food products brought in, material from cases of suspected sickness, and especially and individually to conduct the bacteriological examinations of water, milk, meat, foods and specimens of suspected cases of sickness. 8007

Q. Did you have anything to do with the Health Department in other respects?

A. We were in close touch with the work of the Health Department and received many specimens through the direct work of the Health Department, and assisted them in much of the work by making analyses and examinations of various materials that they used and that they had to do with.

Q. Did your duties require your presence in the various hospitals of the city at any time?

A. Well, as bacteriologist of the department, I did not have to go to any of the hospitals officially, for official duty. The isolation hospital occasionally called upon my laboratory and myself for examination, the men employed there, but I have had other hospital connections.

Q. In the city?

A. Yes sir.

Q. Do you know what the regulations are in the hospitals of Chicago in regard to the treatment of typhoid patients and efforts to isolate them, etc., to prevent the spread of the disease?

8008 A. Yes, I know in a general way. I know specifically about some and I do not know specifically about others.

Q. You mean about some hospitals?

A. Yes sir, some hospitals.

Q. What efforts are made in the hospitals to prevent the spread of infectious diseases and especially the typhoid disease?

A. I think it would be just as well to make this answer somewhat specific because it would be impossible for me to describe all of the methods used for infectious diseases.

Q. Confine it then to the hospitals where you are personally cognizant of the course that was pursued?

A. In regard to some cases, special rules and special rooms are set apart. In regard to other cases the discharges are disinfected.

Q. What diseases are these?

A. Especially the typhoid cases, the intestinal discharges and urine are disinfected.

Q. State the manner of disposing of that kind of material and the disinfecting?

A. The specific way in which it is done?

Q. Yes.

A. Well I can only state positively now for the County
8009 Hospital where I had something to do with it. Something over two years ago, with the recommendation that was made to be carried out at that time and which was instituted. It was to place a quantity of one to one thousand of bichloride solution in the vessels in which the discharges were passed, and they were allowed to stand several hours before they were emptied.

Q. Emptied into the sewers?

A. Yes, before they were emptied into the drains.

Q. And were carried into the sewers?

A. Yes sir.

Q. What effect did that have upon any pathogenic germs that might have been discharged from the patients?

A. That would kill them.

Q. Do you know whether similar efforts were made and similar work carried out in all the hospitals or places where such diseases are treated in this city?

A. Well I cannot state positively from my own personal knowledge of the conduct of these institutions, but in a general way of course, physicians disinfect the stools and urine.

Q. Are there any general regulations upon this subject issued from the head of the health department, or by the Health Department? 8010

A. The Health Department issued a circular regarding the care and disinfection of typhoid.

Q. Do you know the nature and the substance of the instructions given by the Health Department in reference to the disposition of dejecta of persons who may have typhoid fever in this city?

A. Yes, I have seen those regulations and know their contents.

Q. I will ask you to look at this paper and refresh your memory and state what those instructions were as far as you know?

A. In regard to the destruction of the discharges the following recommendation was made:

"If you are so unfortunate as to have a case of typhoid in your family disinfect every discharge as a duty to your neighbors as well as to prevent others of the family from getting poisoned.

Sulphate of copper (blue vitriol) is the best typhoid disinfectant,—one pound (costing ten cents) dissolved in 2 1-2 gallons of water. Keep a pint of this in the vessel for discharges from both the bowels and the bladder. Stir thoroughly for a few minutes; let stand for 15 minutes and the poison will be destroyed. Don't allow any discharges either from the bowels or the bladder to be received or disposed of except in this manner." 8011

Q. In the hospitals where you visited and in your own practice as a physician and from what you know of the practice of other physicians, state if you know, whether these rules were enforced, so far as you know?

A. Well, as far as I know, although I don't believe that this particular disinfectant was used in all cases; its equivalent or something else was used.

Q. Something was used that was equally efficacious?

A. Yes sir.

ADJOURNED until 10:00 A. M., Saturday, October 10, 1903. .

8012 10:00 A. M. Saturday, October 10th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

R. J. BEDFORD,

called as a witness in behalf of the defendants, being first duly sworn by the Comissioner, was examined in chief by Mr. Todd and testified as follows:—

Q. What is your name?

A. R. J. Bedford.

Q. Where do you live?

A. Dahinda, Illinois, Knox county.

Q. Mr. Bedford, did you ever collect any water from the upper Spoon river for Professor J. H. Long, of the Northwestern University?

A. Yes sir.

Q. When did you collect this water?

A. I took one sample November 9th, and the second sample November 24th, and the third sample December 9th, in 1899.

Q. Any samples subsequent to that?

8013 A. Not to my knowledge.

Q. You collected in all, three samples?

A. Yes sir.

Q. At what point in the upper Spoon river did you collect these samples?

A. Let me understand that question.

Q. At what point in the Upper Spoon river, did you collect these samples?

A. At Dahinda, in Knox County.

Q. In what manner did you collect these samples?

A. I collected a gallon sample bottle and a small bottle for microscopic purposes in each case.

Q. How did you get the water into the bottles?

A. I was the possessor of a row-boat and I went out into the river in the boat and took the gallon bottle and immersed it at arm's length under the water and alowed it to fill, and the small bottle was used in the same manner, excepting the cork was not removed until the bottle was under the water and then it was removed, and then tightly corked before taking it out and packing it in the container that they sent out for taking, and according to the directions on the card packed with the main container.

8014 Q. Did you pack the smaller bottle any differently from what you did the larger bottle?

A. Yes sir.

Q. Describe the difference?

A. The small bottle was packed in a tin can with ice, and that can was packed in another larger tin can, and that can was packed in the original container.

Q. Now after you had packed the samples that you collected in that manner, that you have indicated, what did you do with them?

A. I took them to the express office and expressed them to J. H. Long.

Q. How long from the time of taking the samples before they reached the express office?

A. Probably not over twenty minutes.

Q. From whom did you get the bottles in which you collected the samples?

A. I think they were sent from Dr. Long.

Q. Now the card that was placed upon these three samples. will you describe it?

MR. JEFFRIES: It is admitted by counsel for complainant that the card placed by this witness upon the samples of water and attached to the samples, was the same as that exhibited in evidence and known as defendants' Exhibit 4.

8015 MR. JEFFRIES: I move to strike out all the evidence of this witness, because it is incompetent, irrelevant and immeterial, for the reason that the proper number of samples were not taken or analyzed to be of service in determining the sanitary condition of the water, in this river, and for the further reason that the sanitary condition of the water in the Spoon river is not an issue, and for the reasons heretofore stated in objections to testimony in reference to the analyses of water from the various tributaries of the Illinois river.

No Cross-examination. (Signature waived.)

8016 JUDGE SPRINGER: Mr. Comte Max le Couppey de la Forest, who is visiting this country at the instance of the French Government for the purpose of making a report upon the sanitary conditions in the great cities in the United States, is present, and in an interview with him I suggested that we would like to have his views in regard to the conditions existing in the city of Paris, in its water supply, its drainage system, and the manner of disposition of its sewage, or the irrigation of that city, and that we would confine the investigation solely to this point, for the reason that it would be indelicate for him to make any statement in regard to the conditions here in this country, for the reason that he is here to report to his government on that subject.

MR. JEFFRIES: Do you mean to make a witness of him?

MR. DRENNAN: Yes, as to the conditions in Paris alone.

JUDGE SPRINGER: He can be sworn, or he can give his views without being sworn.

MR. JEFFRIES: I object to the statement that was made by Judge Springer going into the record, and if this man is put on the stand he shall go on the stand the same as any other witness in the case, and I make no distinction between this witness and any other witness, in his testimony.

MR. DRENNAN. We explain that we want the record to 8017 show why we don't ask him anything about this country, and why he would decline to answer if asked in regard to his views.

MR. JEFFRIES: He can state why he declines. It is not necessary for counsel to state why he declines.

Witness Prof. Adolph Gehrmann is temporarily withdrawn from the stand.

8018 COMTE MAX LE COUPPEY DE LA FOREST,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer and testified as follows:—

Q. Mr. de la Forest, will you please state, so as to get it upon record, your name, official title and residence?

A. My name in Comte Max Le Couppey de la Forest. My official residence Paris, France, my title, Secretary of the Commission d'Etudes des Eaux, Paris, France.

Q. The meaning of that in English is?

A. The Secretary of the Commission of studies of water,—that is the study of the sewer waters and water supply for the city of Paris, and the metropolitan district of Paris, what we call the Department of the Seine, in France. I am also Secretary of the Society of Hygiene of France, but that is private business. It is not official business.

Q. State whether you held any official position in the Congress of Sanitarians which assembled in Paris during the late Universal exposition in that city?

A. Yes, during the great exposition, in 1900, it was an international congress of hygiene, in Paris, and I was one of the secretaries of this congress.

8019 Q. State what is the nature of your duties in regard to the water and hygiene systems of the city of Paris?

A. For the water and sewage system, I am the secretary of the Commission. We have many meetings every month and I must keep the record of the meetings, and also I must make experiments for this commission, chemical experiments, and also bacteriological, but especially chemical. I am a sanitary engineer also.

Q. How long have you been connected with the government of the city of Paris?

A. Four years and two months.

Q. Will you please state when the city of Paris began the construction of what is known as the irrigation system?

A. The construction was made at many times. We begun this construction in 1868. Experiments were made before,—from 1866 to 1868, in Clichy, near Paris, for the purification of sewers, and irrigation, and after these experiments it showed that the sewage could readily be purified with irrigation, so the city of Paris began, after these experiments were closed, in 1868, to irrigate the fields. In the begining it was a very small area, it was only fifteen acres that was in operation in 1869, in the

place known as Gennevillier, but the areas were not increased immediately because we had a great war between Germany and France, and it was not possible at this time to work,
8020 but in 1872 we began to increase this area and every year
it would be increased, and now,—in 1889 the area of Gennevillier was 1900 acres instead of fifteen acres as in the beginning. The system is very good. The rent of the land before the irrigation was about 45 fracs, or $9.00 an acre, and after the irrigation the land,—the same land would rent for 200 francs instead of 45, or $40.00 instead of $9.00 in the beginning. Soon there was no more room in Gennevillier for further irrigation, so we had to go farther away to a place where the soil was good for irrigation. We went afterwards to Acheres. In the field of Acheres in 1879 we put in operation a superficial area of 2600 acres. The population of Paris increased, and before that we had very many private cess-pools and we built great sewers and obliged all the houses to be connected with the sewers, and so we must always increase the area of the irrigation field.

After Acheres, we built an irrigation field at Mery, of 3,000 acres. This was put in operation in 1898; and after that we built the field at Triel, of 1800 acres, so the amount now of our irrigation fields is 9,300 acres.

Q. At this time?

A. Yes sir, now. Our houses are connected with the
8021 sewer system in Paris. There are in Paris 80,000 houses,
or there were on the 1st of April, 1903. 35,000 of these houses were connected directly with the sewer system. About 25,000 houses have filter cess-pools. The urine and liquids of these filter cesspools go directly into the sewers, and the solids are afterwards emptied into the Seine, in many places near Paris. So we have in Paris perhaps 60,000 houses which were connected directly or indirectly with the sewer system. The population of Paris is now 2,750,000 inhabitants. Of this the residences of six-eighths were connected with the sewer system, so it is about 2,100,000 of the inhabitants that are directly or indirectly connected with the sewer system.

The method of irrigation is not everywhere the same. In Gennevillier, there are little garden farmers who have only a little garden in which to grow vegetables or fruit, and these people can take as much sewage water as they will and when they will. A comparison since twenty years has shown that these people take always an average of the same amount of water every year.

Q. Sewage water?

A. Yes, sewage water; always the same average every year. They average over 40,000 cubic meters every year, per hectare. I will reduce that to gallons. That is 6,500,000
8022 gallons per acre per year; but for the other fields, for
Acheres, Mery and Triel all the land, all the country is the property of the city of Paris, and this land is rented to the great farmers, who give some money to the city of Paris for it, and the people are obliged to take every year the same amount of sewage as before. It is a law, which allowed the building of this irrigation field near Paris; the farmers are obliged to take this amount of sewage and to be sure that the people do that we have many employes of the city of Paris who every day open the gate of the sewer to give the required amount of sewage to the farmers, and we have foremen and engineers to oversee the employes.

I think upon the irrigation question that is all that I can say now.

Q. How is the water that was brought onto the land through the irrigation pipes taken away from the land again and returned to the river?

A. It is not the same everywhere. The field of Gennevillier, the field of Acheres and of Triel are near the Seine river, and the field of Mery is near one affluent of the Seine river, near the river Oise, which empties afterwards into the Seine river. We have drained a great portion of the irrigation field with tile drain and this tile drain empties into little creeks that
8023 afterwards empty into the river Seine or the river Oise.
All the effluent of the sewage will be discharged into the river Siene after purification through the soil, and this purification is good.

In Acheres, Mery and Triel, where the land is the property of the city, the city of Paris has built little gardens, because cities desire always that her works are pretty for the visitors and in these gardens are lakes. These lakes are supplied only with the effluent water from the irrigation field, and in these lakes live many fish, and at the point where the main drain comes into, or empties into the lakes there are springs, but the springs are all of the effluent water. And all of the workmen who live on these different farms,—there are perhaps two hundred or four hundred of these workmen living in this country, they drink only the water of the effluents, and we have a medical survey of these men. All the physicians of the country are connected with the City of Paris and must give weekly reports upon the sanitary conditions of all these men, of all these workmen, and since these different irrigation fields are in operation we have had no typhoid fever or cholera or dysentery, or the diseases which come from water.

Q. Among those who use the water from the irrigation
8024 fields or the effluents, have they not had any of these diseases?

A. No sir.

Q. Have you ever drank any of this water yourself?

A. I have drank it very often, and many times people, foreign people who come to see our irrigation field, whom I, as engineer of the city of Paris would take to the irrigation field, and I drank always the water, and many times the foreign people would drink also.

In 1900, during the International Hygiene Congress in Paris, we made an excursion with this congress to the irrigation field and I and the other engineers drank this water, and many of the foreign people also drank this water.

Q. Will you please state what it was, what reason existed which caused the government of the city of Paris to adopt this irrigation system?

A. There are three reasons. The first reason you might say is only a pleasure reason; the other was a sanitary reason, the third an industrial. Above Paris are little cities and residence towns, to which came in the summer time many people of Paris. There are perhaps three or four hundred thousand people who come from Paris during the summer to live, near Paris, twenty or thirty miles below, from Paris.

Q. Below the city?

8025 A. Below the city, and all these residences are built on the banks of the river, and the banks of the river Seine are very pretty, many trees and little hills; it is very pretty, and very agreeable, but when the city of Paris began to discharge its sewage into the Seine, there was a great smell, the water was very dirty; it was no more possible to bathe in the water and every year the condition got worse and worse, and that began in 1860 and from 1860 to 1870, that was always worse and worse. That is the pleasure reason, if I can say so.

And the second reason is the sanitary reason, and that is that in summer when the river Seine is low the people who lived near the Seine had in time a little fever not typhoid but malaria or something like that. Not quite malaria, but a little fever,—intermittent fever, at the point where the river Seine was low and where the river had many branches.

And the third reason is an industrial reason if you can say so. There are a great deal of people who live below Paris, between Paris and perhaps sixty miles below, engaged in the fishing industry, and all of the fish died, because there was too much sewage in the water, and every year the condition of the fish became worse and worse, because the amount of the sewage that was discharged into the river was in summer diluted in a very small amount of water. 8026 The dilution of the sewage in the Seine was only at this time one fifteenth or one-eighteenth. That means one part of sewage was diluted in fifteen times that many parts of Seine water, or eighteen parts of Seine water.

Q. How far down the river did this pollution extend at that time, during that period?

A. Perhaps 35 miles, about 35 miles below Paris, in the summer time. I have here the different chemical analyses of the river Seine, above Paris, in Paris, below Paris, and at many points below Paris, from five miles to 100 mies below Paris.

Q. Miles or kilometers?

A. Miles. That was before the irrigation was begun. One of the analyses is for 1847 and the other 1869, when we were ready to begin the irrigation in the field of Gennevillier and I also have here the organic matter and the total nitrogen in the water. You can see that where the main sewer emptied at this time into the river Seine, it was 25 parts of total nitrogen in the water per 100,000 parts of the river Seine, and 42 miles below, near the city of Maneese, it was only 1.4 instead of 25 parts.

8027 I have also the figure for the organic nitrogen at the same point where the main sewer emptied into the river Seine. It was 7.2 parts of organic nitrogen per 100,000 parts of the river Seine, and near the city of Meulan 40 miles below Paris, it was only .4 of a part of organic nitrogen per 100,000 parts of water of the river Seine. So we can see that at this time the river Seine had a self-purification after 45 miles, at this time in 1869.

Q. How many people, inhabitants of the city, were draining or depositing their sewage into the river at that time, directly or indirectly?

A. At that time it was perhaps only 800,000.

Q. Now how many inhabitants in the vicinity of Paris, residing below the city on the banks of the Seine, are there who deposit their sewage into that river?

A. Now?

Q. Yes now, at this time?

A. At this time I have said that the city of Paris has 2,750,000 inhabitants. The people of the city of Paris do not discharge the sewage into the sewers and into the river Seine, they discharge it into the irrigation field,—six-eighths of the inhabitants discharge sewage into the irrigation field, and the other two-eights sell their sewage to a company who make fertilizer of it.

8028 Q. They sell it to persons who use it for a fertilizer?

A. Yes. But the suburbs of Paris discharge all their sewage directly into the Seine. . The suburbs below Paris and above Paris also discharge their sewage directly into the Seine, and that was a population of about 1,100,000 inhabitants in 1899, and that is the latest figure which I can find; but you can say perhaps now since four years it has increased and it is now perhaps 1,300,000.

Q. That number whose water-closets in the houses and the wastes from the houses go into the river Seine at this time?

A. Into the river Seine at this time.

Q. What do you say Mr. de la Forest, was done with the sewage of the two-eighths of the city of Paris whose sewage was not carried off into the irrigation fields; what became of that?

A. They have fixed cess-pools in their houses and a company will empty these cess-pools one or two times per year and will make fertilizer with all the matter that was in the cess-pool.

Q. Do they pay for that or are they paid for getting it?

A. They must pay something to the company, and the company makes money.

Q. Do you know how much is paid per family to the company?

A. No, they pay per cubic meter, which is emptied, and it is not everywhere the same price. In one ward of
8029 Paris it will be so much, but I do not know how much.
I think in some parts of Paris it is two francs per cubic meter, but it is not the general price. I do not know the general price. I know that for some wards in Paris it is two francs per cubic meter.

Q. Do you know how much the irrigation plant has cost the city of Paris up to this time?

A. Gennevillier cost	5,200,000	francs,
Acheres,	10,500,000	francs,
Mery,	10,800,000	francs,
Treil,	15,000,000	francs.

Buildings for housing of machinery and general expenses 5,000,000 francs.

Q. What does it cost per year to maintain the service, and keep this plant in operation?

A. I am sorry, but I have not here the cost of maintainance. I have only the cost of the elevation of the sewage, to put the sewage into the irrigation field, and this cost is something high, because we must elevate the sewage very much. The pumping of the sewage comes very high. This cost in 1901, was 2,967,500 francs, or $593,000.

MR. JEFFRIES: That is the cost of operation?

A Only for the pumping. I have not the other figures
8030 here, and the other cost is very high, because I have said
to you that in Acheres, Mery, and Triel we have a great many employes who must open every day the gates of the sewers, and we have perhaps 200 of these men, and I do not know how much these people cost.

Q. What class of employes must you obtain for this purpose?

A. They are what we call municipal employes.

Q. Yes, but as to their qualifications?

A. The name in French is what we call skilled workmen.

Q. Well informed people?

A. Yes, well informed, and they do not work alone. There are all the time foremen and superintendents,—many superintendents who keep an eye over the work and then three engineers above the superintendents,—sanitary engineers.

Q. State, if you please, what measures are taken by the city authorities of Paris for the purpose of ascertaining the character and condition of the water in the Seine above and below the city at this time?

A. We made also experiments upon the water,—chemical analyses and bacteriological experiments.

Q. They are making continually these experiments?

A. Yes, continually we make analyses and examinations of the drainage of the different irrigation fields, and also the same analysis is made of the water of the river Seine at
8031 Paris, above Paris and below Paris. Below Paris we take
two samples every week, five miles below Paris, ten miles and fifteen miles below Paris, two times every week, and the effluents of the different drains in the different irrigation fields are also examined for bacteria and for chemical compositions, every week, one or two times or three times; not always the same.

Q. What is the condition of the water in the river Seine at various seasons of the year at this time?

A. The high water in the river Seine, you mean?

Q. Yes. What is the condition of it as to purity at this time?

A. Oh, the river Seine at all times is polluted by many cities which are above Paris, so when the river Seine flows through Paris the river Seine is too bad; it is not possible to drink the water of the river Seine in Paris, but below Paris the river Seine—I said in Paris the water of the river Seine is too bad to be drunk, but fish can live in the river Seine, but below Paris, after it has emptied into the river Seine the sewage perhaps of 1,000,000 or 1,200,000 inhabitants, the condition of the river Seine is very much worse below Paris than above Paris,

and in summer, immediately above Paris especially, fish
8032 can no more live in the water of the river Seine. We
have spent in the city of Paris a great deal of money to build the irrigation fields of Acheres, Gennevillier, Mery and Triel, but that is not sufficient, because the cities above, discharge sewage directly into the river Seine, and we have now a metropolitan commission to purify the sewage of the suburbs of Paris, because the conditions of the cities that are above Paris and near Paris, are in very bad condition in summer, and in summer also the fish cannot live immediately below Paris.

Q. What is the volume of the water in the Seine below Paris in the lowest stages of the river, in the summer time?

A. In the summer time the lowest stage is 60 cubic meters per second, that is 126,000 cubic feet per minute.

Q. In the low stages?

A. In the lowest stages, in summer.

Q. How much higher than that does it get in the winter months?

A. In the ordinary months it is 190,000 cubic feet per minute.

Q. Can you state from your knowledge, obtained officially in Paris, how far down the river at this time the effects of the sewage from the suburbs of Paris disappear?

A. I have said that in 1869 when 800,000 people discharged their sewage in the river Seine, the purification of the Seine
was perhaps—the zone of purification was perhaps 45
8033 miles below Paris, but now we have perhaps 1,200,000
people who discharge their sewage into the river Seine, and the zone of purification is something more far below Paris. The zone is, I think,—I am not quite sure,—it is perhaps 55 miles below Paris. I have no figures here, but I think that it is so, 55 miles. I have the figures in Paris, but I have not them here. I am almost sure that it is 55 miles from Paris, and I must say that the sewage is diluted now in the proportion 1 to 20. One part of sewage to 20 parts of the river Seine.

Q. Will you please explain the manner in which the city of Paris now obtains its water supply?

A. We have in Paris a double water supply. We have two kinds of water in Paris, and in each street and in each house we have two kinds of pipes. We have drinking water and clean-

ing water. The drinking water is for drinking purposes and to cook with and bake bread with, and for all the preparations of food. The people are obliged in Paris, when they make food, to use the drinking water to make food in the restaurants and everywhere. The cleaning water is used for cleaning the streets, for running elevators or to clean the house, to clean the courts of the houses, to clean the carriages and also for industrial use and
industrial purposes.

8034 Q. And for flushing the water-closets of the private
houses?

A. Yes, also the water-closets. But not always for water-closets, because this water has not always pressure enough, but in two or three years we will have more pressure to this water and in two or three years all our water-closets will be supplied with river water.

Q. You use this river Seine water for everything except drinking purposes and cooking purposes?

A. Yes, but for industries, for the great industries in Paris the people have built private artesian wells, which are 2,000 feet deep and the great industries of Paris do not buy water from the city, but have their own artesian wells. The cleaning water comes from the river Seine, Marne, Ource and also in a very little amount from artesian wells, which belong to the city; but these artesian wells are only one-fortieth part of the total amount of the water that is used. Also we use in Paris drinking water that comes from springs. The springs are far away from Paris, the water comes to Paris over aqueducts. The shortest aqueduct is 60 miles long, and the greatest in length is 110 miles long, and now we are bringing into Paris new springs, and the aqueduct
will be 200 miles long. And this water comes to Paris
8035 with gravity and comes to the tops of the buildings also
by gravity. We furnish each day 24 gallons of drinking
water and 45 gallons of cleaning water per capita.

Q. How much of this water is furnished by the river Vanne?

A. The river Vanne furnishes one-third of the amount of the drinking water. Vanne is not a river; there are springs which are in the valley of the river. We say sometimes in common language, river, but it is not a river, it is a spring. In the valley of the river Vanne there are springs, and they get the water from the springs. The different springs of Vanne which supply Paris are the springs of the valley Vanne, the valley Avre, the valley Loing et Lunain, and the valley Dhuys.

8036 CROSS-EXAMINATION, by Mr. Jeffries.

Q. Is it the intention of the city of Paris to further extend its sewer fields?

A. It is not quite sure whether it will be a sewage field or septic tanks or the aerobic system, because these septic tanks, or the aerobic system do not cost us so much as the irrigation field. Two years ago the chief engineer of the sewers of Paris was sent to England to study the septic tanks, Mr. Launay, and this year I was sent to America to see what the American people are doing for sewage disposal, because we must increase our system of purification of sewage in Paris. I have said to you that now it is only 60,000 houses that are connected directly or indirectly with the sewerage system, and 20,000 houses are not directly connected with the system and we must build a purification plant for those 20,000 other houses and this purification plant can be a field irrigation or a septic tank or something else. I don't know now what it will be in some years.

Q. Will you please state what the object of the authorities of Paris is in treating this sewage?

A. Its object is to purify the Seine river between Paris and 55 miles below Paris, where the self-purification of the
8037 river is not great enough.

Q. How far is it from Paris to the sea, by the river Seine?

A. 250 miles, perhaps.

Q. Is there any income from the sewage fields?

A. The city of Paris has two sources of revenue for the sewage. First, each house that connects with the sewage system must pay a tax, and second the irrigation fields are rented to farmers who give a great sum of money, but I think that in all it costs something to the city of Paris, because we must elevate the sewage very much and so we must increase often the tax for the connection from the houses to the sewer to do that. It costs nothing to the city.

Q. Then each of the citizens makes his own connection?

A. Not in all. A part of the connection is built by the city.

Q. And is charged up to the individual?

A. Yes, sir.

Q. Now, the city of Paris keeps a separate account, doesn't it, of its sewage plant and all the expenditures and all the sources of revenue?

A. Yes, sir.

Q. Now, do you know about how the expenditures compare with the receipts?

8038 A. No, because that is not my part. I am sanitary engineer, and I know nothing of that. I am very sorry to say that.

Q. As a citizen of Paris. The question is discussed among the people there, isn't it?

A. I have heard only by the papers and the papers do not always say the truth.

Q. I understood you to say that the farmers paid a handsome price, a very large price for this sewage from the field?

A. Yes, because they produce very good crops.

Q. They produce splendid crops?

A. Yes, sir.

Q. And therefore there is a good market for them?

A. Yes, a good market. I must say something. Now, it is no more possible for the farmer to produce all kinds of crops. They won't allow them to grow the crops which people eat raw without cooking, such as raw fruit and salad, and it is no more allowed to make the crops of wheat that will grow very near from the soil, because we have seen that people who will eat the crops that grow very near to the soil, which is covered with the sewage, and which has in it the bad bacteria, and the people who eat that, afterwards can be sick. The board of health of Paris first, and afterwards several boards of health of France, prohibited the use of the soil for fruits and crops 8039 which grow very near to the soil, that can be eaten without cooking, and since the board of health, two or three years ago, made this prohibition, or regulation, the condition for the farmer is not so good as before, because before that they had very good strawberries and slaw and salad, which they cannot any more have now. I must say that I and my family before the board of health said that, for the last fifteen years, we have never eaten any Paris raw salad because the greatest quantity of salad in Paris came from the irrigation fields, and I say it is very dangerous to eat the salad.—Not so now, because now the salad comes no more from the irrigation field, but comes from other gardens or fields and does not come any more from the irrigation fields, but before that it was very dangerous to eat the salad from Paris.

Q. Now, they can grow potatoes, you say, from these fields?

A. Yes, because you eat always cooked potatoes and you will not eat the shell of a potato, but it will be dangerous to eat the raw shell of a potato but nobody ever does that.

Q. Now, you say this order was made by the board of health fifteen years ago?

A. Three years ago.

Q. Three years ago the sewage fields were a source of considerable revenue?

8040 A. Yes, sir, a good revenue. Considerable is putting it a little strong, but a good revenue. And I can say something upon this, that it is not in Paris, but it is something which we have studied as a board of health. In the center of France some time ago there was a lady who was sick, three years ago, and Metchnikoff, a great physician of Paris, came to see what was the matter with this lady and he gave a laxative to this lady and found in the excrement, eggs of a little animal, of an intestinal worm that lives only in Switzerland, and so he said to this lady: "You were in Switzerland this summer." She answered: "No, I have not been in Switzerland for twenty years; I have not left my house here," and the doctor made an investigation and he saw that in the house of this lady there was a gardener, and he had come from Switzerland in the last two or three months, and this gardener made his excrement upon the salad bed, and used it as a water-closet and he had in his intestines this worm and this lady had eaten the whole salad and had the worm afterwards.

Q. Do you know how much revenue per acre they derive from these sewage fields?

A. No, I can say only for the field at Gennevillier. That doesn't belong to the city. That belongs to private people, and there they have crops like strawberries and salad and
8041 asparagus. This kind of crops will give very much more money than the other crops, perhaps ten times more, and I know that for Gennevillier, the rent of the soil is 300 francs per

acre, and that is six times as much as they get for good soil in France.

Q. I understood you to say that the effort was now being made to purify in some way the sewage from the suburban towns around Paris?

A. It will be the sewage of 1,200,000 people, which is directly emptied into the river Seine and the sewage of perhaps 500,000 people who live near Paris.

Q. So then they intend to utilize the sewage of those two suburban places?

A. Yes, sir.

Q. Comprising 1,600,000?

A. Yes, sir.

Q. And to provide companies and they will treat the sewage in that way?

A. No, the sewage will be purified in an irrigation field, a septic tank or with other scientific methods.

Q. Now, they are going to do away with the sale of it to the private companies?

A. Yes, sir.

8042 Q. And they are going to treat it in some way that has not yet been determined upon?

A. Yes, sir.

Q. After that has been treated, it will comprise practically all the population of Paris?

A. And the suburbs of Paris, yes, sir.

Q. The idea of Paris now is, in making this investigation, to obtain the most approved and scientific method of treatment?

A. Yes, sir.

Q. With a view of removing all of the harmful substances from the sewage?

A. Yes sir.

Q. How long is the sewage permitted to remain on these fields before it is taken in charge by the farmers?

A. It is immediately taken in charge by the farmers night and day. An employe of the city of Paris will open the gates of the sewers, just as the man will say to this man, one day in one part of the field and the other day in the other part, and none of the sewers will remain without being used. They are used immediately. It goes through the sewer and is immediately discharged upon the field.

Q. In other words, every farmer takes his part each day?

A. Yes, sir.

8043 Q. Or every other day or every third or fourth day?

A. Every day each farmer has a certain amount of sewage. Every day every farmer must choose so much sewage, so much as is said by the engineer, and that is the amount of sewage as set by the law of Paris. It is 40,000 cubic meters per hectare. I have given it to you before in acres.

Q. Now, every farmer must take this rain or shine?

A. Yes, sir.

Q. Whether it rains or not?

A. And it is sure that he takes that. It isn't the farmer that opens the gate; it is the employe of the city of Paris, so we are sure that each farmer will take what he is obliged to take.

M. le Couppey de la Forest.

Adjourned until 2:00 p. m., same day, Oct. 10.

8044 2:00 p. m., Saturday, October 10th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

J. J. STITES,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer, and testified as follows:

Q. Please state your name, residence and occupation?

A. J. J. Stites.

Q. Where do you reside?

A. Pontiac, Illinois, on the Big Vermillion river.

Q. What is your occupation?

A. Well, I am a physician.

Q. State whether you ever took any samples of water from that river, and if so, at whose instance they were taken?

MR. JEFFRIES: We object to the testimony of this witness as to the taking of samples from the Big Vermillion river, for the same reasons stated in our objection to the testimony of other witnesses about the taking of samples of water for analyses from other tributaries of the Illinois river.

8045 Q. Now, proceed to answer.

A. I did, sir.

Q. At whose instance?

A. At the instance of J. H. Long, of the Northwestern University.

Q. When was that?

A. It was in November and December, 1899.

Q. State what instructions, if any, you received from Dr. Long in regard to the taking of those samples?

A. Well, I received printed instructions on a card which I followed implicitly. The instructions, with the exception of the sample for the bacteriologist, did not differ from any other samples that I collected for the University of Illinois.

Q. Please look at that paper and state whether that contains the instructions, and the blank that you were requested to fill up in making the return of the samples taken?

A. That is a report of the first water taken on November 9th, 1899, in which I found the temperature of the water 49 degrees Fahrenheit, and the temperature of the air 50 degrees. It was taken above the mill-dam in the Vermillion river and about a mile perhaps above where the sewage enters the same river.

8046 Q. State whether that is the form of blank that was furnished you for filling up with the data and whether on the back of it is printed the instructions which you received?

A. The same, sir.

Q. State whether you followed the instructions upon that card?

A. I did, sir, implicitly, with a great deal of care.

Q. State whether you filled this blank yourself?

A. I did, sir.

Q. And whether the statements contained in this card as filled up by you contain a true statement of the condtions which are reported?

A. They do, sir.

Q. Did you follow the same course in regard to each of the three samples you took?

A. Yes, sir, precisely the same.

Q. What kind of bottles did you receive from Professor Long, and what did you do with them after they were filled?

A. I received a case containing two bottles. One I would suppose would hold a gallon,—a ground glass stoppered bottle, and then that was, I should think about six ounces, a bottle with a ground glass stopper, covered with a rubber wrapper, that was enclosed in tin, and that was enveloped after the 8047 water was in it, in cotton and placed in this little tin and closed and then pounded ice, or crushed ice was put around it, and it was sealed up hermetically.

Q. Then what did you do with it?

A. Put it in the case and shipped it to Dr. Long.

Q. By express?

A. Yes, sir.

Q. State how you took the sample from the water; what did you do?

A. Well, I immersed the bottle about,—well up to my elbows, below the surface of the water before I removed the stopper and allowed it to fill, and I don't know whether he said to empty it three times or not, but I did empty it three times to be sure that it was thoroughly rinsed with the river water. Then after filling it the fourth time I emptied out enough just to leave a narrow space, about an inch, below the stopper, and put the stopper in it without touching my fingers to anything only the crown of it and tied the cloth over it, and when I took it to the express office, after tying the tag on, I had a knot tied right on top of the cloth and sealed, and the seal of the express company put upon that knot so that it could not be disturbed without breaking the seal, and if so, I suppose the doctor would not examine it.

8048 Q. Did you put upon the card that you returned, the date at which you took the sample?

A. I did, upon the card that accompanied the sample.

Q. Was that the correct date at which the sample was taken?

A. Yes, sir.

Q. How many samples did you say you took from the Vermillion river?

A. Three.

Q. Now, will you please state where that river has its origin, and whether it passes through Pontiac, and where it empties into the Illinois river?

A. Well, I don't know that I can tell you just exactly where it has its origin.

Q. Well, generally?

A. I think one branch of it is over in Ford county, I am not certain about that, but the most of it is from springs and creeks in Livingston county.

Q. How large a stream is it at Pontiac?

A. Oh, perhaps 150 or 200 feet wide.

Q. Does it receive the sewage of Pontiac below the place where you took these samples?

A. Below the place, yes, sir.

8049 Q. And what important towns does it pass through before it goes to the Illinois river?

A. It passes through Streator and I suppose La Salle.

Q. No, La Salle is on the opposite side of the river, isn't it?

A. Yes.

Q. It goes through Streator and empties into the Illinois river, and enters the Illinois river opposite La Salle?

A. Yes, sir.

JUDGE SPRINGER: These cards have already been offered as defendants' Exhibit No. 17.

MR. JEFFRIES: And it is admitted that they are of the same character as defendants' Exhibit No. 4.

8050 CROSS-EXAMINATION, by Mr. Jeffries.

Q. How many samples did you collect at this point?

A. Three of each kind, three of the water for chemical analysis, and three for bacteriological examination.

Q. How near together were they taken?

A. Right from the same spot.

Q. I mean with reference to the time of taking the three samples?

A. Well, I always took them in the large bottle first.

Q. No, with reference to the date, the time?

A. All the same date, same hour.

Q. Yes, but you took two samples each day?

A. Yes.

Q. Now, how far apart were the days on which those samples were taken?

A. Well, now, I think the first one was taken on the 9th of November, and the second one on the 24th of November and I ought to remember the date of the third in December, but I don't because I fell in the river that day and got wet and like to froze to death before I got home, but I can't tell you the date.

JUDGE SPRINGER: Is it on the card?

8051 A. I think it is. I think it is December 8th.

MR. JEFFRIES: They were all taken about two weeks apart?

A. Yes, two weeks apart.

Q. Did you take any samples in the spring time?

A. No, sir, that is the only time I took them.

Q. Did you take any samples in flood time?

A. The second one was taken in a few days after a very hard rain, but the river was not raised any perceptibly,—not more than an inch or two, but it was quite muddy.

Q. Was there ice on the water at any time?

A. There was the last time, thin ice, about a quarter of an inch in thickness.

Q. How long had it been frozen?

A. I think a day or two.

Q. And you only took three samples during the whole time?

A. That is all.

MR. JEFFRIES: I move to strike out the evidence of this witness for the reasons stated in my objections to his testimony.

(Signature waived.)

8052 B. F. LONG,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer, and testified as follows:

Q. What is your name?

A. B. F. Long.

Q. Where do you reside?

A. Joliet.

Q. What is your occupation?

A. Engineer.

Q. What kind of an engineer?

A. Stationary engineer. I worked at the steel works.

Q. Did you at any time take any samples of water from the river at Joliet?

MR. JEFFRIES: What river?

JUDGE SPRINGER: From the Desplaines river at Joliet, at the instance of Dr. Long?

A. Yes, sir.

Q. When was that?

A. Well, it was the summer of 1899 and the summer of 1900.

8053 Q. What instructions, if any, did you receive from Dr. Long?

A. Well, he came down there and I seen him personally. He told me how to take them,—to dip the large bottle down about ten or twelve inches under the surface of the water and leave it fill up to about an inch of the top and then cork it up; and the small bottle the same way, and pack it in ice—tied a little rubber over the top after being corked, and packed in ice and sealed and then I shipped them by express. The bottles I generally rinsed out about once, or dipped them down and put water in them and rinsed them out, and then filled them up.

Q. Would you recognize the cards that you filled up if you would see them?

A. Yes, sir.

Q. Look at these and state whether those are the blanks that you received from Dr. Long, and whether the handwriting in there is yours?

A. They are the same, and my handwriting.

Q. What is the first date then?

A. That I cannot tell.

Q. It is on the card there, isn't it?

A. Yes, sir, September 3rd.

Q. That was the beginning of it, then?

8054 A. I lost the cards or burned them up,—or the express receipts. I had them and I either burned them up or lost them.

MR. JEFFRIES: It is admitted by complainant that the cards now produced to this witness are the same cards produced to Professor Long while he was upon the stand, and testified to by him as having been received with the samples of water from this witness.

Q. JUDGE SPRINGER: Now state whether you followed the instructions on the back of that card in taking these samples?

A. Yes sir, I did, as near as I possibly could.

Q. State whether the entries made by you in your handwriting upon those cards state truly the conditions which you reported or intended to report of the acts which you performed in taking these samples at that time?

A. Well the interest—I took full interest in it.

Q. Please state whether these state the truth, whether these are the true conditions that you found there?

A. This is true. I put down the truth, nothing but the truth. I had no object in doing anything dishonest.

Q. You have stated I believe how you collected this water. What did you do with the samples after you took them away from the river?

8055 A. I took them straight to the express office.

Q. How did you pack them?

A. I packed the little one in ice. The large one was just in a box, packed with excelsior around it.

Q. What did you do then with it?

A. I took them to the express office and then shipped them.

Q. Shipped them addressed to whom?

A. To Dr. Long, 2421 Dearborn Street.

Q. You have not stated exactly the times when these specimens were taken.

A. Oh, they were all taken in the evening between five and half-past six o'clock. I would have to get them to the express office by seven.

Q. And the dates upon which these were taken are all noted upon these cards?

A. Yes sir, the dates. The dates were put on every collection I made.

CROSS-EXAMINATION,

By Mr. Jeffries.

Q. At what point in the Desplaines river did you take these samples?

A. The first samples, that was in 1899, I took them above the basin in the neighborhood of Ruby Street bridge, that 8056 is the upper bridge. Sometimes it was north of the bridge and sometimes south of it. I managed to take the samples always north of the bridge. The dredge worked here in that vicinity all summer, and my instructions was from Dr. Long to manage to take the sample above the bridge.

Q. Now with reference to the mouth of the drainage canal, and its entrance into the river Desplaines, where did you take the samples?

A. Well at that time it was emptying below there. It emptied down right opposite the blast furnace, if you know where that is.

Q. And you took the samples above?

A. Above that.

JUDGE SPRINGER: That is the Illinois and Michigan casal, you mean, the first one?

MR. JEFFRIES: No, we are talking about the drainage canal.

A. Well, it wasn't out of the canal I took it. I didn't take the sample out of the canal. That water laid dead. I had no instructions to take it out of the canal.

JUDGE SPRINGER: Out of the Desplaines river?

A. I took it out of the Desplaines river, and of course the canal run in there, but was above the locks, the river and the canal was partly together. Then there was a part of the 8057 river that ran down at one side a little west of that and emptied down further. Since then it has been better.

Q. If the canal was opened, where did you take the samples with reference to the mouth of the canal?

A. At Jefferson Street bridge, above the sewers.

Q. Where is Jefferson Street bridge, with reference to the mouth of the canal. Is it above or below?

A. The canal is away up above Jackson Street.

Q. Then you took the samples after the canal was opened, out of the water that had been mixed with the water coming from the drainage canal?

A. Well, I took them below where the mouth was. The water ran into the canal and down the river both.

Q. The water ran from the drainage canal?

A. Yes, exactly.

Q. Into the river above the point where you took the samples?

A. Yes, above, exactly.

Q. In other words you took samples below the place of discharge of the water from the canal into the Desplaines river.

A. Well the discharge of the canal in the Desplaines river is away below that—south of that.

Q. South of what?

8058 A. Now here, the mouth of the canal is up north of Jackson Street, and it empties out into the river again away below Jefferson Street, and the river and the canal runs together.

Q. The drainage canal

A. Well yes,—well the drainage canal or whatever you call it, the old river bed—there is only one stream along there, whatever you might call it, the drainage, the river, the canal the whole three runs together.

Q. Well, I understand that. Did you take samples out of the mixed water of the Desplaines river and the drainage canal?

A. Yes sir, the mixed water.

Q. Did you take any samples out of the Desplaines river before it had been mixed with the water of the drainage canal?

A. Well I can't answer that, to answer it truthfully. The canal water was mixed with the other water of course, when I took the samples.

Q. But you never went far enough above the Desplaines river to get beyond the influence of the water from the canal?

A. Well, I think not.

Q. Now how did you take these samples?

A. I always took the large bottle first.

Q. Took the cork out?

A. Took the cork out and filled it full of water within about an inch of the top.

Q. You would take this big bottle and take the cork out
8059 and put it under the water?

A. I always put it under the water before I took the cork out, in order that it wouldn't get any of the surface water.

Q. How far under did you put it?

A. Ten or twelve inches.

Q. Then you would bring it out, put the cork in and rinse it, would you?

A. Yes.

Q. Put the cork in after you brought it out of the water?

A. After I brought it out. It was plumb full to the top when I brought it out. Then I would pour some more out of it. I kept it under the water until it was perfectly full, running over, and pulled it up and threw some of the water out.

Q. Pulled it right up with the mouth to the surface of the water?

A. Yes, I had my hand—

Q. Did you have your hand around the neck of the bottle?

A. Yes, sir.

Q. Both the small and the large bottle?

A. Yes.

Q. Just jerked them right up out of the water?

A. Pulled them up out of the water. I managed to take it where it was clear.

Q. Did the surface water get in as you pulled them up?

8060 A. How would it get in when it was full?

Q. Well, it was exposed to the surface water, was it not?

A. Well, the bottle was exposed to it, certainly.

Q. And the mouth of the bottle?

A. The mouth of the bottle was full just the same as if you had a cork in it. You can't get no more in them after they are full enough to run over.

Q. Are you right certain that the surface water didn't crowd some of the water out?

A. I am satisfied of that. I would bet my life on that part of it.

Q. Now, where would you hold the stopper when you was rinsing it, what would you do with it?

A. I generally laid it down at first, rinsed it out, and then I would hold it in my hand, after I had dipped the bottle down and took the stopper out. My instructions was not to touch the bottom of the cork.

Q. When you laid it down where did you lay it?

A. Set it up on end, right on a stone or on a rock.

Q. Dry stone, was it, or rock?

A. Dry.

Q. Wind blowing and dust flying?

A. No, I don't know as there was any wind. Of course
8061 there was air.

Q. Do you know there was no wind; do you know there was no dust?

A. Well, there is always dust blowing, too.

Q. Would you stake your life on that?

A. No, I wouldn't stake my life on that because there is always dust blowing.

(Signature waived.)

8062 PROF. ADOLPH GEHRMANN,

resumed the stand for cross-examination by Mr. Jeffries, and testified as follows:

Q. Doctor, how much does the determination of the numbers of bacteria show in regard to the purity of the sample of water?

A. The determination of the number of bacteria present in water is a small part of the examination of water for purity. It indicates a degree rather than an absolute fact.

Q. Depending considerably upon the examiners, and the source of the bacterial ingredients, does it not?

A. Yes, the kinds are more important than numbers.

Q. And the kinds, so far as pathogenic bacteria are concerned, depend largely upon the source of the pollution. Isn't that true?

A. Upon the source of the pollution?

Q. Yes?

A. Well, they can to a degree depend upon the source of pollution.

Q. How large a quantity is one cubic centimeter—put it in cubic inches, or teaspoonfulls?

A. About four cubic centimeters make a drachm. It is about a quarter of a drachm.

8063 Q. How would it compare with an ordinary thimble?

A. Well, I don't know as to thimbles. I have no experience as to thimbles.

Q. Now, how many cubic centimeters from each sample bottle sent you did you ordinarily examine?

A. We very rarely for the colony count examined a cubic centimeter. These examinations were made in water known as dilutions. That is, it became necessary, owing to the large number of bacteria, present, to dilute the water one hundred times or a thousand times, and then take a portion of this dilution for the plate cultivation, so that in none of the instances was a cubic centimeter taken.

Q. And you diluted the water according to the impurities that it contained, or according to the number of bacteria that it contained?

A. Yes, we diluted it according to our previous preliminary examinations that had given us an idea of how many we might expect.

Q. So that in waters that contained more bacteria than others according to your previous examinations, you made greater dilutions?

A. Yes, those where we expected to find more we diluted more than the others.

8064 Q. What was the average amount of dilution that you used in the samples taken from the Illinois river?

A. Well, the Illinois river, of course, at the different points, it was different. I could not give you anything that would indicate an average amount of dilution. One hundred and one thousand were the usual dilutions for points around Henry, Averyville and Chandlersville, Beardstown and Grafton, and one thousand and ten thousand for points like Wesley City, Pekin and Morris—points as high up as Morris.

Q. So that where you used the thousand parts in dilution, you simply analyzed the quantity of bacteria in 1-1000 part of a cubic centimeter of the water that was actually taken fom the river?

A. That would be the procedure, yes.

Q. And if you diluted it 100 parts, you would examine 1-100 part of a cubic centimeter of water, taken at the various places for the purpose of determining the number of bacteria per cubic centimeter?

A. Well, that is not altogether true. We might take two or three hundredths. The multiplication would not necessarily always be by 100. It might be 50. In some cases we might have taken more water than one one-hundredth.

8065 Q. But any of the instances in which you took 50 or 100 or 1,000, you would examine 1-50, 1-100 or 1-1000 of the water taken—per cubic centimeter of the water taken from the river?

A. Yes, the calculation would indicate that. It might not be absolutely that. It might be a little more or a little less.

Q. But that is the way the calculation was made?

A. Yes.

Q. Now, Doctor, was this small quantity of water examined sufficient to determine with accuracy the bacterial condition of the whole canal or river from which it came?

A. I might confess that an examination of this kind shows a degree of accuracy that gives results that can be comparable with other results made about the same time or in the same line of work.

Q. But it is not such a determination as might be considered the result of an exact mathematical calculation or science, is it?

A. It is scientific, but it is not like mathematics.

Q. It is not an exact science?

A. I shouldn't say that it was as exact as mathematics.

Q. Professor, state whether or not each particular sample

8066 would be necessarily a representative of all the water in the river at that point, or at the point where taken?

A. I believe it would be representative for that time and moment that it was collected.

Q. You don't mean by that, do you, Professor, that if there should have been certain kinds of pathogenic germs at that point that they would have been disclosed by that sample?

A. No, not at all, the count is simply for numbers, without any reference to the kinds.

Q. And you confine yourself to the count with reference to the character?

A. Yes.

Q. Now, might another sample taken from nearer the shore or nearer the bottom of the river, or a few hours later, have given different results?

A. They could give different results to a degree.

Q. Now, Doctor, does bacterial count alone afford sufficient information upon which to base an opinion of the sanitary condition of a body of water?

A. No, I don't think that the count in itself will decide as to the sanitary condition.

Q. Assuming, Doctor, that the same number of bacteria are detected in two samples of water, sent you for examination,
would you as a bacteriologist be able to say that any two
8067 bodies of water from which they may have been derived,
are of the same sanitary quality?

A. No, I could not from a bacterial count alone, make such a statement.

Q. Is it true—or is it not true that one might have come from a typhoid infected lake or river and the other from one free from such infection?

A. The two samples having the same amount may have come from many different localities. The number indicates nothing with regard to the locality from which it comes, in itself, except as far as the numbers indicate bacterial activity in that sample.

Q. Then it would indicate nothing as to the presence of pathogenic germs?

A. No, it would not show pathogenic germs.

Q. Would it indicate anything as to the absence of pathogenic germs—the presence or absence of pathogenic germs?

A. The bacterial count is not a statement of quality—it is distinctly a statement of quantity. It has nothing to do with the kinds.

Q. In your examination yesterday, Doctor, you testified that the bacterial purity of water examined by you from the Illinois river at Grafton, and from the Mississippi river at the
same place, was about the same. Just what do you mean
8068 by that?

A. I was speaking at the time about the numbers of bacteria present, and the results indicate that as far as the numbers of bacteria and the activity of bacteria present in the water in these two localities, is approximately the same.

Q. Then bacterial purity as you have stated does not necessarily mean sanitary purity?

A. No, bacterial purity is not recognized as its sanitary condition, except as far as the general activity of decomposition that is taking place is concerned, which has a slight bearing on the question as to purity or impurity.

Q. You have stated that the bacterial purity of the water of the Mississippi at Jefferson Barracks and at the chain of rocks was of about the same bacterial purity. Doesn't this show as heretofore stated by you that the term "bacterial purity" used in this sense has little or no significance—sanitary significance?

A. It has only the significance of the numbers of bacteria present, and the activities of the bacteria present and the extent of the decomposition that has taken place in given samples of water at these two points.

Q. Doctor, do you recognize any general relations between numbers and purity in water?

8069 A. Yes.

Q. Hundreds, bacterially speaking, indicate more purity than thousands?

A. Yes, that is true.

Q. The counts?

A. Yes, sir.

Q. That is, basing it on bacterial counts, and yet those hundreds may contain more pathogenic bacteria than the thousands, may they not?

A. That is true. The numbers in themselves are simply estimations of quantity and not quality.

Q. Now, are you acquainted with, and you are, I suppose, with the number of bacteria in Chicago tap water?

A. Yes, sir.

Q. Are those not hundreds rather than thousands?

A. We have made a great many examinations and found that the averages for some years were thousands and the averages for other years hundreds.

Q. Aside from averages, what would you say as to single examinations, as applied to the tap water of Chicago?

A. Single examinations have been as low as tens, and single examinations have been as high as 10,000.

Q. Have single examinations been as low as ten and as 8070 high as thousands practically at the same time, at the same tap?

A. No.

Q. But for considerable periods they might run hundreds, might they not?

A. Oh, yes.

Q. You have examined bacterially the water from Lake Michigan, have you not?

A. Yes.

Q. Have you examined the water taken from the mouth of the Four Mile crib?

A. Yes.

Q. And from the other cribs?

A. Yes, sir.

Q. State whether or not, Doctor, you examined the water from the mouths of these cribs during, prior to or subsequent to any increase in the number of typhoid fever cases in the city of Chicago?

A. I had occasion during the past year to examine the tap water from the various taps including the Four Mile crib at the time when there was an increase of typhoid fever in the city of Chicago, during June and July and extending into August.

Q. JUDGE SPRINGER: What year?

A. Last year. My examination of the water did not con- 8071 tinue after the last of June or the first of July, but I examined the water up to that time myself. There was an increase in typhoid during the months of June and July in the city of Chicago.

Q. Was this a general increase all over the city?

A. No, it was not a general increase.

Q. To what part of the city was it confined?

A. 19th ward.

Q. And what crib do they get their water supply from?

A. They get it from the Harrison Street Pumping Station which is a mixed water,—Four Mile water and old Chicago Avenue water.

Q. And the Chicago Avenue water comes from how far out in the lake?

A. That is a two mile tunnel.

Q. So it was a mixture between the two mile tunnel water and the four mile tunnel water?

A. Yes, it is more four mile water than two mile water; it is some Chicago Avenue water.

Q. Now, did you examine the water from the mouths of those two tunnels during that time?

A. Yes, sir.

Q. Had you examined it prior thereto?

A. Yes.

8072 Q. State whether or not you discovered any typhoid bacilli in those examinations?

A. No, I did not.

Q. Did you think it strange that you did not?

A. No, I did not.

Q. You didn't expect to find them, did you, Doctor?

A. I didn't have any reason to suspect that there would be typhoid bacilli in the water at that particular time. There was nothing that would indicate any special reason for the presence of typhoid bacilli.

Q. And yet it was there?

A. I don't believe it was.

Q. Then you think that epidemic did not come from the water?

A. I am quite certain that it did not.

JUDGE SPRINGER: From what water?

A. Lake water.

Q. MR. JEFFRIES: Did you ever examine the water of Lake Michigan when typhoid was common all over the city?

A. No, sir. That is an epidemic,—what I would consider an epidemic. No, I never had occasion to examine it during an actual epidemic.

8073 Q. Did you ever examine it when it was commonly supposed by physicians and others to be coming from the water?

A. Such cases as occurred in the city from time to time and could be looked upon as coming from the water, I examined the water because I had been examining it continuously for a number of years.

Q. Doctor, is it your opinion that the typhoid fever cases and epidemics of Chicago have been caused by the using of the water from Lake Michigan or not?

A. The epidemics that I have any definite knowledge of outside of the one of the past year, were due to the water.

Q. Were due to the water?

A. Yes.

Q. Did you not examine the water during any of those epidemics?

A. No, not what I would call an epidemic.

Q. Do you know whether or not there was any great change in the bacterial contents of the water during those epidemics from that which it had been prior thereto, so far as shown by laboratory experiments?

A. There were no laboratory experiments made that I know of.

Q. Do you attribute any part of the typhoid fever in Chicago since 1894, to the water supply of the city?

8074 A. Yes, I would say that about one-half of the cases under all circumstances came from the water supply, and they come from the water supply owing to two or three causes. There has been continuously a certain amount of flow of sewage into the lake, especially along the south side, from 35th street, south, so that infectious matter could be carried out to the cribs, and there has been dumping of dredges along shore almost continuously during these years.

Q. And that is going on now, is it not?

A. That is going on at the present time, yes.

Q. Now, during all this time from 1894 down have there been any bacterial changes in the bacterial condition of the water from Lake Michigan as taken from these various cribs?

A. There have been a few times when the figures would vary with a degree, that is, different years would be different. I don't consider that there is any great variation at any time.

Q. But in those variations and as the bacterial contents would vary, so far as the numbers of bacteria are concerned, would you notice a corresponding variation either prior to or subsequent to the variations, in the number of typhoid cases in Chicago?

A. I have noted some slight differences. In one small increase in typhoid that occurred in 1897 where the bac-
8075 teria were more numerous and the water was worse at that time, and there was an increase in typhoid two or three weeks later. That is the only one that I can recall that is very definite.

Q. How does the water in Lake Michigan during all of these years that analyses have been made by you and in your laboratory taken from the various cribs, compare in respect to bacterial count, and bacterial purity with the averages which you have obtained from Grafton?

A. They are better.

Q. Doctor, have you any means of telling the source of the bacteria in the counts which you found in the water of Lake Michigan while you were making these various examinations?

A. I am very certain upon many occasions that they came from the dredgings that were deposited in the lake, because I had occasion to follow the dredge, or follow the water for as much as an entire afternoon, as to its movement in the lake.

Q. What connection, doctor, do you place upon the stirring up of the lake by these dredges, and this dredging, with the typhoid fever cases in Chicago and what significance do you attach to it?

A. In the first place the dredging referred to is not one of stirring up, but it is the emptying of dredgings from the scows into the water, and my view is that a proportion of the
8076 typhoid comes from these dredgings, but not any material proportion of the typhoid.

Q. Where does it come from?

A. The typhoid that we have, that is, that portion of it that we can attribute to the water, comes from the direct transfer of infectious matter from the sewers to the cribs.

Q. But you take into consideration both as a means of producing the typhoid cases, both the dredging and the direct passage?

A. I think the dredging is a party to it, but to a less extent.

Q. When you said the counts were better in your previous answer, in comparing the bacterial counts of the water in Lake Michigan, than that of the Illinois river at Grafton did you mean that they were lower in the waters of Lake Michigan?

A. Yes, lower.

Q. Doctor, you testified I believe that your bacterial counts were made upon agar plates?

A. Yes sir.

Q. At what temperature were they incubated?

A. We kept them at 18 to 20 occasionally,—about that temperature.

8077 Q. That is 18 to 20 centigrade?

A. Centigrade. It was the intention to maintain it exact, but it ranged from 18 to a little over 20.

Q. They were not at the blood heat were they?

A. No, it would be known as moderate room temperature.

JUDGE SPRINGER: 37 is blood heat?

A. Yes sir.

MR. JEFFRIES: You stated doctor, that the bacillus prodigiosus that you found in your laboratory might have come from a contamination of some kind, did you not?

A. I didn't say, as I remember it, that I found it in my laboratory.

Q. Well, that is true. Where did you find it? I have forgotten.

A. As I remember it I said that I found it in examinations of different kinds and so on.

Q. Did you have any reason to believe or to know where it came from?

A. No, except that when I really tried to get a culture of bacillus prodigiosus, I took plates where there was decomposed vegetable matter in considerable quantity found, for instance, a garden, cabbage field, or something of that sort.

Q. Did you find it there?

8078 A. I found it there, yes.

Q. You believe then that it lives wild in the United States, do you?

A. I believe so, yes.

Q. It is very rare in nature is it not?

A. It is not common. Sometimes it appears in considerable numbers at a given point, as a general thing it does not; it is not prevalent as many other organisms.

Q. Is that the case in this country?

A. Yes, in this country that is the case.

Q. Doctor, in view of the fact that the sewers of Chicago into Lake Michigan have produced typhoid fever in Chicago, what significance do you place upon the rules of the Board of Health in regard to the different disinfections of typhoid excreta always proving effective?

A. My view in regard to these particular points, the disinfection of stools is that we have now in the educated physicians, that I believe we have in this country, the trained nurses, and others, an almost universal disinfection of the stools during cases of typhoid fever. In the majority of cases the spread of typhoid fever comes after the patient is convalescent, and the urine which often contains large numbers of typhoid bacilli, that
the patient or the person can deposit and spread about
8079 for several weeks or months after he is actually out of
bed, when he is out of the control of any regulations or management.

Q. And may that not also be true before the doctor and nurses have been called in?

A. Less true than afterwards.

Q. But it may be true to some extent?

A. It may be true, yes.

Q. Are there not many so-called walking or un-recognized cases of typhoid fever in which the disinfectant is never applied?

A. Not as many as formerly, because with blood examinations we could single out those cases much better than previously, and anyone who has a continuous fever for a time is pretty apt to find out what it is in the course of a few days, or a week.

Q. May they not be of such a character as not to come under the observation of the doctor at all?

A. There are cases of that kind, yes.

Q. Isn't it a fact doctor, that even when it is applied in private families, it is often done in an unskillful and inefficient way?

A. You mean the disinfection of the stools?

Q. Yes, disinfection of the stools and urine.

8080 A. Well, there is always a possibility of not having a person who appreciates entirely the value of disinfection, and so it is not carried out to its full extent. That is always a risk, a possibility that might exist.

Q. How far out in Lake Michigan from the Lake Front at Chicago does bacterial contamination sometimes extend, according to the examinations which you have made?

A. The examinations that I have made as to the extent of the contamination, had been at various points along shore, different distances out, and especially out in a direct line east from the mouth of the Chicago river. The degree to which the sewage and shore contamination would extend into the lake varies a great deal and varies rapidly at times, depending upon wind movement and the amount of rainfall, as to the flushing of the sewers. I have some recorded examinations that I could present as to the results. Some of these show that there is no evidence of any pollution any further out than two miles, and again we have evidence of pollution by the presence of excessive numbers of the bacteria and colon bacillus, ten miles out.

Q. Isn't the sewage entering Lake Michigan highly diluted before it enters the intakes of the city waterworks?

A. Yes, it is highly diluted.

Q. An extreme dilution, is there not?

8081 A. Undoubtedly an extreme dilution of sewage matter.

Q. Doctor, have you ever used in water examinations the so-called Guinea pig test?

A. Yes sir.

Q. For the purpose of determining the presence of pathogenic germs?

A. Yes.

Q. Is this test capable of revealing the presence of or the absence of the typhoid fever germs?

A. No, it will not necessarily show the presence of typhoid bacilli. It might under some circumstances, but not as a routine method.

Q. Do they show the absence of it?

A. I don't believe it would positively in all cases show the absence.

Q. Do you regard that as an important test?

A. Yes, I consider that an important test in water examinations.

Q. Why was it not used in your examinations of the water of the Illinois river?

A. The examinations that were made were made in the way they were made on account of a mutual agreement between a
number of parties to which I was a part, and the con-
8082 census of opinion was to conduct them in that way. That
is all I know about it. The difficulties of animal experiments may have a possible bearing on a question of that kind.

Q. Now doctor, state in the language of Mr. Todd, so that an intelligent layman can understand, just what is implied or meant by the term pathogenic germs?

A. I don't like to term them germs. I never use that unless I have to.

Q. Organisms then?

A. Micro-organisms.

Q. Pathogenic micro-organisms?

A. Bacteria. A pathogenic micro-organism is one that under conditions is able to alter physiological conditions.

JUDGE SPRINGER: Is what?

A. Able to alter or change physiological conditions.

Q. MR. JEFFRIES: It is not necessarily a disease germ?

A. Alteration of any physiological function has in it at the bottom the disease or pathological condition.

Q. But it may not be an infectious disease germ?

A. Infections? No, it might be a toxic disease.

Q. What do you understand is meant in hygiene by the term saprophytic bacteria?

A. The saprophytic bacterium is one that is capable of living upon dead organic matter.

8083 Q. Are not pathogenic germs capable of living on dead material in laboratories?

A. And hence also, saprophytic. Yes, they can be what we call facultative, that is, they can live either upon dead material or as parasites upon living material.

Q. Is there then doctor, any sharp line between saprophytic and pathogenic germs, or bacteria?

A. The sharp line comes when you arrive at the question of the alteration of the physiological conditions. The minute that you come to that line of changing a physiological condition or altering it in any way, you reach the point of pathogenicity. It may be in an extremely light degree, or a very marked degree, leading to the death of the individual, but as soon as you get any alteration due to these things you have what can be considered, and is considered, a pathogenic property.

Q. Can it always be accurately ascertained or determined, as applied to the human system, when a germ ceases to be a saprophyte and becomes pathogenic, or vice versa?

A. It is limited by the ability of our instruments, and the precision in our chemical methods, or biologic methods. There is the possibility of the presence of changes that our present methods cannot give us an accurate idea of at this time, at least the beginning of them. After they have advanced to a
8084 certain point they become obvious, but the beginnings are often very difficult to trace, and our methods give us no exact knowledge of it.

Q. In your analyses of the water down the Illinois river, doctor, in 1899, and to which you have testified in chief, did you record the number of colon bacilli that you found or merely the presence of the colon?

A. I recorded simply the presence of the colon bacillus and not the numbers, for the reason that in order to get at the numbers one has to make quite a large series of dilutions, and separate tests, and I found that the amount of work I had that I couldn't follow this out accurately enough to decide upon it, and I made those tests for qualitative determination.

ADJOURNED until Monday morning, October 12, 1903, at 10 o'clock.

10:00 A. M., Monday, October 12, 1903.

8085 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ADOLPH GEHRMANN,

resumed the stand for further cross-examination by Mr. Jeffries and testified as follows:

Q. Professor, how long were you connected with the city health department after these examinations about which you have testified, were made?

A. One year and seven months.

Q. Were these analyses all made by yourself?

A. They were made under my immediate supervision, with the assistance of two or three assistants who worked with me. I made a great many of the counts, and the direct examinations personally. I supervised the work personally throughout.

Q. Now who were those assistants?

A. I had an assistant of the department, Kierueff, working with me, and Dr. Kilburn, who was assigned especially for assistance in this work. They made the culture media and 8086 cleaned the apparatus and kept the work going, as an assistant would.

Q. Now those are the only examinations of the water from the Illinois river that you made?

A. I made some analyses or some examinations once before

Q. Did you make any since that I mean?

A. No, not since then.

Q. Have you been down the Illinois river recently?

A. I was down the Illinois river from Chicago, through the length of the river to St. Louis in September.

Q. You are not connected with the Health Department now then are you?

A. No, not at the present time.

Q. I understood you to say you were professor of hygiene in some college or institution here in Chicago?

A. Yes, I am professor of hygeine and bacteriology in the College of Physicians and Surgeons, the medical department of the University of Illinois.

RE-DIRECT-EXAMINATION,

By Judge Springer.

Q. Professor, what was the effect of taking the 12th and 22nd Street sewers from the lake and turning them into the Chi-

cago river, and what effect did this have on the typhoid
8087 death rate in Chicago, if you know?

MR. JEFFRIES: Turning them into what river?

JUDGE SPRINGER: The sewers were emptying formerly into the lake and they were turned from the lake and turned into the Chicago river, and then out the other way, and I ask him the effect of this upon the typhoid fever rate of the city.

MR. JEFFRIES: We object to the question as not proper re-direct examination, not having been brought out by the witness on direct examination.

A. These two sewers were relaid in 1898 and 1899, the work was completed in the fall and winter of 1899, and the drainage of all of the district as far south as 31st Street in this city was changed from discharge into the lake to discharge into the river, that is westward. And the records of the following year show that 1900 is the best year that the city has had as regards typhoid fever. It is due in part to the removal of this amount of drainage from the lake, because these sewers were in such a position that their discharge would pass more nearly opposite the important intakes.

Q. What effect has the removal of the intakes further out into the lake had?

A. The removal of the intakes further into the lake has reduced the amount of typhoid fever in Chicago because of
8088 the greater dilution, and greater time required for the sewage matter to reach the intakes.

Q. Will you state what was the cause of the typhoid increase last year, of which you spoke in your testimony on cross-examination. By last year I mean the year 1902.

A. The increase in typhoid last year was mainly a local epidemic in the Nineteenth Ward, and was due to the overflow of the portion of the basement and a pump well of the Harrison Street pumping station during the early summer and also to the presence of open vaults in this ward, as shown by the investigations of the members of Hull House and published in the report of the City Homes Association. In the overflow of this pump well as stated, it was found that a sewer connection had over flowed and was the direct cause of the flooding by sewage from the street sewers.

Q. Do you know what proportion of the deaths in the city during that year were in the immediate vicinity of this break in the sewer, or overflowing of the water pipe?

A. Out of 402 deaths recorded, 180 were in this immediate neighborhood. That is something over 35 per cent., practically I don't know the exact figures.

Q. How great an area do you include in this estimate as being in the immediate vicinity?

8089 A. The 19th ward—the area of which I don't exactly know.

Q. That is what you refer to when you say in the immediate vicinity, you mean in the 19th ward?

A. Yes sir, the 19th ward.

Q. Are the wards in this city constructed mainly in reference to the population or the area in territory?

A. They are entirely arbitrary. I don't know how they reach their ideas about the wards. They are arbitrary.

Q. You don't know what proportion of the poulation of the city was in that ward?

MR. JEFFRIES: I suggest that that is a matter of record.

A. Yes. Off-hand I could not state. Probably 30,000 or 40,000 people.

Q. JUDGE SPRINGER: If sewage should pass into the lake at this time or if sewage is now passing into the lake why is there not more typhoid fever in Chicago?

A. The intakes are at such a distance from the shore that the dilution of the sewage is so great and the time for the passage to the intakes and back to the poulation is sufficient to give opportunity for destruction in a considerable portion of the infectious matter.

Q. From your studies of the water supply of Chicago and from your knowledge of what has been done in reference 8090 to this supply, will you state what improvements, if any, have been made in the system from time to time?

MR. JEFFRIES: Now we suggest that that question is not permissible under any of the rules of evidence, as far as re-direct-examination is concerned. It is not brought out in chief by counsel for defendants and therefore he has no right to bring it out in re-direct.

JUDGE SPRINGER: The reason for submitting this question is that it relates to the question of typhoid which was brought out on the cross-examination.

A. Up to the years 1890 and 1891, the intakes for the obtaining of water were not over two miles from shore, the furthest being two miles. Other intakes were less than a mile from shore, and up to that time there had been a continuous excess of typhoid fever in the city. In the epidemic of 1890 and 1891, and a portion of 1892, which was due to the special taking of water from the shore intake, the extension of the intakes was completed, and from that time a marked decrease in typhoid was noticeable. In 1899 the work of re-laying the sewers at 12th and 22nd Streets, was completed and a further decrease in typhoid resulted.

Q. In your cross-examination you used the term "infectious matters" in water. Will you please give your definition of that term as you understand it?

8091 A. By infectious matter I mean portions of the structures or tissues or excretions of the individual containing the micro-organisms that will lead to infection.

Q. In one of your answers on cross-examination you stated that you objected to the use of the term "germ," the word "germ," will you state what your objection to the use of that word is?

A. The term "germ" is a very indefinite term. Germs mean simply the origin of anything, in a very general way, as for instance, the germs of freedom, or any obscure, indefinite thing that gives rise to anything in speaking of disease conditions, we should confine ourselves to the definite objects or causes that have to do with the origin of such diseases.

Q. Your objection then is that it is too general when applied to micro-organisms?

A. Yes.

RE-CROSS-EXAMINATION,

By Mr. Jeffries.

Q. Doctor, if all the sewage of Chicago was turned into Lake Michigan today, would it not in your opinion increase the number of typhoid cases in the city of Chicago?

A. Undoubtedly the turning of all of the sewage would
8092 increase typhoid in the city.

Q. I will ask you doctor, if the typhoid micro-organisms have not a better chance for sedimentation in passing out into the lake and the Four Mile Crib, than they do in a stream that has a continuous current?

A. I doubt whether I could reach any definite information on that point, from my knowledge of Lake Michigan, I know that it is not a quiet body of water by any means, and as far as streams are concerned, it would depend entirely upon the rapidity of the stream and the conditions involved in the stream, a comparison would be extremely difficult for me to draw; therefore I would be almost without any data upon which to draw a definite conclusion as to a question of that kind.

Q. When is sedimentation most rapid?

A. When the water is quiet.

Q. That is shown in the laboratory, is it not?

A. It is a principal of physics.

Q. Do you have any idea of the extent of the dilution of typhoid bacteria or micro-organisms in the water of Lake Michigan when the average typhoid conditions at Chicago existed?

A. Yes, I have an idea. It must be extremely great, because I cannot find the typhoid bacillus in the water.

8093 Q. And you have made numbers and numbers of examinations of the water of Lake Michigan for that purpose?

A. Yes sir, I have.

Q. A great many more examinations of that water—of the water of Lake Michigan than you made of the Illinois river?

A. Yes, more examinations.

Q. Was there anything in the water of Lake Michigan in your examination that indicated to you that it was not potable?

A. During the long series of examinations that we have made, and a comparative study of the returns of deaths from typhoid fever in the city, we have reached a certain degree of recognition, of the finding from bacteriologic and chemical examinations, which indicate to us that the water at one time is more infectious than it is at other times.

Q. But, doctor, taking into consideration the bacterial analyses alone, without reference to your knowledge of the effect that the use of the water has had upon the people of Chicago, confining yourself now strictly to the bacterial examinations, did you find anything that would lead you to believe that it was not a potable water?

A. The findings of the colon bacillus has given us an idea as to the potability at different times,—variations in potability. 8094

Q. And that without respect to the number of the colon per cubic centimeter?

A. In my work it has been in reference to the continuance—

Q. The continual presence?

A. The continuance of finding it; the greater frequency of finding it.

Q. And you reason by bacterial analogy that if you find the colon present, that other pathogenic germs are present?

A. The presence of the colon bacillus is recognized as indicating sewage matter,—

Q. Yes, but of what importance—

JUDGE SPRINGER: Let him finish the answer.

MR. JEFFRIES: I beg your pardon, doctor?

A. Indicating sewage matter and its more continual presence increases the possibility of other pathogenic organisms possibly being present.

Q. In other words, the presence of the colon leads a bacteriologist to believe that there are other pathogenic micro-organisms present while they may not be found in the sample examined, yet on account of the immense dilution, pathogenic germs or micro-organisms of more serious moment are present though in a more diluted state than the colon, is that not true? 8095

A. The presence of the colon bacillus gives bacteriologists the idea of suspicion in regard to a particular sample of water. It is suspicious.

Q. But professor, when you find the colon bacilli present in that water, that you are examining, and which water you know has produced typhoid fever among the people using it, do you not then conclude that the presence of the colon is in part significant of the presence of the typhoid?

A. It is in part significant of the presence of other organisms.

Q. But the best test, professor, of the sanitary condition of water is the effect that it has upon the people using it, is it not?

A. Yes, that is a better index than the simple finding of the colon bacillus.

Q. Doctor this dilution—does dilution remove pathogenic micro-organisms from a lake or running stream?

A. Dilution?

Q. Yes?

A. Pure and simple?

Q. Pure and simple dilution?

A. I don't think that dilution would remove them; it would aid in their destruction.

8096 Q. In what way?

A. It would bring about a more rapid dissemination and breaking up of the particles derived from indivduals that are sick with the various diseases, and in that way would liberate the micro-organisms from the protection of particles, so the destructive effects might be more easily operative in bringing about their ultimate death.

Q. Then you are of the opinion that the typhoid micro-organisms or the disease producing micro-organisms will live longer in highly contaminated water than water that is free from contamination; is that the way I understand you?

A. No, I don't say anything of that kind at all.

MR. JEFFRIES: Read the previous answer.

(Answer read).

Q. And that liberation of the solids from the protective effect would be caused or produced by the friction in the running stream; do I understand it in that light?

A. No, we are speaking now about dilution itself.

Q. Dilution itself, yes?

A. Now leaving aside other reasons, for it is the same thing that might occur under other conditions, in dilution itself, infectious matter would be disintegrated more quickly than if it remained as a little mass of dried or semi-dried ma-

8097 terial in some particular spot, for instance on clothing, or in a small drop of water.

Q. Are you of opinion that disease producing micro-organisms will live longer in highly contaminated water than in water that is less contaminated?

A. No, I believe that in highly contaminated water, where decomposition and the action of saprophytes is very active, the pathogenic organisms, or disease producing organisms are more quickly destroyed.

Q. Now doctor, does not dilution merely separate the disease producing micro-organisms rather than cause their disappearance in the water. When we speak of dilution pure and simple, is not that what it means?

A. Yes, dilution is the separation of the individuals, and of course with dilution we have agencies operative which lead to the death of certain numbers of them.

Q. Doctor, assuming that a typhoid bacillus was deposited in an ordinary well, would you recommend the use of that water knowing that the bacillus had been deposited there?

A. No, I should not.

Q. If a typhoid bacillus had been deposited in a hogshead of water containing 65 or 70 gallons,—one typhoid bacillus,—you knowing that that bacillus was there alive and virulent, would you recommend the use of that water for domestic purposes? 8098

A. In reply to this question, I have some views of the typhoid organisms, and typhoid infection that I believe would be necessary to explain before arriving at any positive answer. I do not believe that there is very much danger from even a few single free typhoid bacilli. I must draw a distinction between infectious matter and free, single typhoid bacilli, and in a case where I knew positively that one typhoid bacillus had been placed in a certain quantity of water, without knowing anything of the conditions under which that water were to be placed, the amount of organic matter in it, the possibility of the rejuvenation and growth of them---of this single typhoid bacillus, of course I should say that the water was not potable. But under conditions where I knew that there would probably be no multiplication of that typhoid bacillus in the water,---no, as it were, incarnation of the amount of infection present, I should not myself have any hesitation in drinking the water.

Q. Because you believe that even though you would swallow that one germ, it would not affect you?

A. I do not believe it would.

Q. Might not that germ be placed in some other condition which would produce—after it had been drawn into the household, that would produce typhoid?

8099 A. Oh, it is possible that we might have incidental circumstances accompanying the condition, which would lead to a condition in the bacillus, and the condition under which they were placed, after a time that it might make it possible to infect individuals again.

Q. Isn't it possible that there might be certain conditions in the human system, a broken down system, run down system, or weak system that would be conductive to the multiplication of those typhoid bacilli when the one germ has been swallowed by the person, or in other words, isn't it as likely for that germ to have got in contact with the proper medium in the system of the person swallowing it, as it would if it had been taken into a laboratory and grown upon a media, or taken into a household and accidently placed upon the proper media at the proper temperature and multiply?

A. This question involves so many possibilities that a direct answer without qualification to my mind is a matter that is not entirely possible. It is without doubt true that a single bacillus can be taken and through the proper circumstances either without the body first, or within the body afterwards, can be brought to such a condition that it will bring about infection, but still we must recognize that the closer the micro-organism comes from infected individuals, to the time they 8100 get into the second individual, the more certain will be the infection, and that the conditions within the individual must be exceptional from a chemical, from a mechanical and from a biologic standpoint, in order that a single, or even a few free separate micro-organisms shall find conditions which will be suitable under those circumstances for the bringing about of the infection of the second party,—the second individual.

ADOLPH GEHRMANN, M. D.

THE COMMISSIONER: It being now 11:00 A. M., Chicago time, which is noon, Washington time, and the limit set by the Supreme Court for the taking of testimony in this case, but a motion for the extension of that time being now pending before the Court, it is understood and agreed by counsel that if the Court grants said motion the testimony hereafter taken until the Court acts on said motion, shall be and become a part of the record, with the same probative force as other parts, but if the Court deny the motion, the testimony hereafter taken shall be, with the consent of the Court, considered as a part of the testimony taken in this case.

(Motion granted by the Court Oct. 13, 1903.

F. S. BRIGHT,
Commissioner.)

8101 D. B. BISBEE,

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer and testified as follows:

Q. You may state your name, residence and occupation?

A. D. B. Bisbee, LaGrange, Illinois. I am a chemist.

Q. Where were you educated, at what college or institution?

A. The college is the agricultural college of Iowa.

Q. How long did you attend that college?

A. I took the full course, four years and then took a post-graduate course afterwards.

Q. How long was that?

A. Altogether it was six years and a half, I was at the school.

Q. Were any of your studies especially directed to the subject of chemistry?

A. Yes; I made that my special branch right straight through.

Q. What studies have you pursued since that post-graduate course in reference to chemistry?

A. Why, no systematic course of study. It has been simply

what I read in periodicals and books, and what I take up
8102 from meetings and conventions and things of that kind. No regular course of study was laid out.

Q Have you performed any chemical work since you left the college, in the way of making analyses of water?

A. Yes.

Q. Please state what?

A. For four years, beginning in February, 1896, I was the assistant city chemist of Chicago and was engaged all that time in water analysis. I made some water analyses before I became city chemist. I don't know how many now. I haven't any idea, but I made some examinations before. I was familiar with the subject, and since 1900, since the fall of 1900, I have been chief chemist of the city and the water examination has been under my direction. I made part of the examinations, but they have all been under my direction up to the present time.

Q. How many chemical analyses of water were made each day, by you during that period?

A. Well the water—of the water there were never less than four and they were from that number up to 12 made each day. I should say about an average of seven samples a day, that is six days in a week.

Q. How long a period did that cover?

8103 A. Four years.

Q. Did you make chemical analyses of other liquids than water?

A. Yes, a large number of ices, and then various other liquids?

Q. Milk?

A. Yes, sir, a large number of milks, a great many more milks than water, of course.

Q. That is part of your general work?

A. Part of my general duties.

Q. How were the samples brought to your laboratory, or where did you get them, of water that you analyzed during this period?

A. They were brought to the laboratory by various people who collected them and they were brought in five-pint glass stoppered bottles. That is the waters for the examinations. These samples I mean were all samples of city water, taken from the various pumping stations throughout the city.

Q. Yes, that is what I am speaking of now. Are you still connected with the chemical department of the Board of Health of Chicago?

A. Yes sir.

Q. Are you acquainted with Dr. Adolph Gehrmann?

A. Yes.

8104 Q. Did you hear any part of his testimony in this case?

A. I heard parts of it, yes.

Q. Dr. Gehrmann stated that certain tables which he read in evidence, numbered, beginning with No. 159 and including consecutive numbers down to and in cluding 196, were made jointly by him and yourself. Would you recognize those tables now if you should see them?

A. I think so.

Q. Please look at the tables to which I call your attention, beginning with No. 159 and ending with 196, being the tables to which Dr. Gehrmann referred, are they those which you participated in making?

A. Those are the tables that were drawn up from my notes, that of Streams Examination work wihch I did jointly with Dr. Gehrmann.

Q. What part of those tables was it that you made yourself?

MR. JEFFRIES: We object to the witness stating in the record his having made any part of the tables which were read in evidence by Dr. Gehrmann, for the reasons stated in our objection to their being read into the evidence at the time, and for the further reason that there is nothing within the science of chemistry that can determine the sanitary condition of water for drinking and domestic purposes, and for the further 8105 reason that a sufficient number of samples were not taken and examined with a view of making any determinations whatever that would be reliable or carry with them any degree of credibility or probative force, and for the reason that the samples of water were not taken with reference to flood stages and low water stages, winter seasons and summer seasons and the various changing conditions of the Illinois river or the Desplaines river, and the Chicago drainage canal, and for the further reason that the defense has proven by Professor Long that certain living micro-organisms existed in the water analyses made by him chemically, though he could not determine their character, whether they were pathogenic or non-pathogenic, and for that reason the science of chemistry throws no sufficient light upon the sanitary condition of the water for drinking and domestic purposes, that could be relied upon by a tribunal passing upon the condition of the water in question and such testimony, the evidence of such tables and such analyses would have no probative force whatever.

JUDGE SPRINGER: I desire to suggest that this objection goes to the weight of the evidence and not to its competency, and it would be more properly addressed to the Court than to the Commissioner.

8106 Q. (Question repeated).

A. All of the tables with the exception of the notes under headings "Height of water", "Temperature of water", "Temperature of air", "Presence or absence of coli, and the number of bacteria per cubic centimeter."

Q. Wherever in these tables then the height of the water, temperature of the water, temperature of the air, are noted, state where those figures were obtained by you?

A. They were obtained from the paper or the tag which came with each sample of water. This paper tag was filled out; it was a blank form which was filled out by the water takers.

Q. Now please state in what condition the water samples were received by you, the analyses of which are recorded in these tables?

A. The sample was received by me from the various express companies in wooden boxes, these boxes had two, four or six compartments, according to the number of samples that were sent in them, taking the two compartment box as a sample, one of the compartments held a gallon bottle of water for my examination, and the other compartment held the bacteriological sample. The chemical sample, the gallon bottle, was sealed by means of a rubber cloth, which was fastened over the stopper and had a wire running through the various holes in the
8107 cloth around under the stopper of the bottle, and sealed

with a lead seal. This was simply to prevent the stopper being removed after being sealed, without either the seal or the rubber cloth being destroyed, so as to show that it had been unopened. Then this bottle was packed by means of excelsior or other packing in the compartment of the box. Do you care about the description of the way the bacteriological sample came?

Q. Yes?

A. The bacteriological sample came in a four ounce, I think, bottle, which as far as the stopper was concerned, was sealed in the same way, as I remember, that is, with a rubber cloth over it, and sealed by means of the lead seal, and a wire. Then this bottle was put inside of a tin can which was just large enough to hold it, and packed in there with cotton. Then this tin can, after being fastened up, that is the top put on, was packed in a large tin pail with about one gallon capacity, and this pail was then filled with ice. It came to me with part ice and part water. Then this gallon tin pail was packed in excelsior in the second compartment of the box.

Q. Were all the packages you received during the periods mentioned in these tables packed in that way?

A. Yes.

8108 Q. I see on table No. 159, for instance, that you put on the left hand column, serial numbers, what do those indicate, 33 and so forth?

A. That was the number on the small tin tag which was sealed on each large bottle, that is, one tag was stuck on the wire before it was sealed, and that was the number stamped in the tin tag. Now that number corresponded to a number written on the paper tag, which also accompanied the sample. It served simply as a means of identification of the sample.

Q. Did you put those numbers on yourself, or did you take them from the cards that came from the water takers?

A. They were taken from the card that came from the water taker.

Q. I notice in the next column there, 1899 collections, are certain dates, showing I presume, the dates of collection. Where did you get those data?

A. Those were also taken from the card filled out by the water taker.

Q. Did you correctly enter the dates according to the dates found on the cards furnished by the water takers?

A. Yes sir.

Q. Now I call your attention to the second column—"examination", who entered those dates?

A. I did.

8109 Q. What do you mean to convey by the dates mentioned in that column?

A. Well, that was the date upon which each sample,—that is the date for instance, July 3rd, is the date upon which sample No. 31 was started in the laboratory, the analysis was started, or the date upon which the examination commenced.

Q. In the next column I see the word "Turb'y". That refers to turbidity?

A. Turbidity.

Q. Who made the entries in that column and in the next column from that, "color" and "odor," the next four columns. Who made those entries?

A. I made all four of them.

Q. Now are the explanations at the bottom of the column correctly stated, "H" standing for heavy?

A. Yes, they are all correctly stated.

Q. "V. H." very heavy and so on?

A. Yes sir.

Q. How did you determine these qualities, turbidity, sediment, color and odor?

A. The turbidity I simply gave a relative description of—well, I can hardly call it the opacity of the liquid, but it was the solid matter, or the suspended matter rather, which would 8110 not settle. It was either there as silt or very fine clay, or something like that, but it would not settle, at least for several days.

The sediment refers to the amount, (and under the sediments I gave the relative amount of matter) solid matter which would settle to the bottom of the water, and which was on the bottom of the bottle at the time I received it. All of those four entries were made on my notes immediately on the receipt of the sample. Two of them before the bottle had been opened, then the odor immediately on opening the bottle and the color, wherever there was any which was determined, was determined immediately.

Q. Those three ascertainments then were not made from any chemical analyses but from merely the physical appearance?

A. Those are all physical appearance. Yes, they are all physical appearance.

Q. What are we to understand by these various designations which you have entered in this table with regard to the character of the water?

8111 MR. JEFFRIES: That is objected to for the same reasons stated in our objection to the witness being examined with reference to the tables that have previously been read into the record by Dr. Gehrmann.

A. I hardly know what you mean.

Q. Read the question again.

(Question read).

A. You mean those four designations?

Q. Yes, these four designations?

A. Why, they don't mean anything particularly, except the first two columns, the relative amount of the undissolved matter and the odor might give a person an indication as to some of the impurities in the water. That is as to the source of some of the impurities. The color does not indicate anything in regard to a water, except possibly certain kinds of contamination, from vegetable matter.

Q. Muddy, for instance?

A. Well, mud, yes. You couldn't see any color to it, but there was a kind—there was a color to it, but at the same time it wasn't a yellow, it wasn't anything. The word "Muddy" expressed the appearance of the water, even after it was filtered, better than anything else.

Q. These various entries then are not accurate ascertain-
8112 ments of physical conditions, even, but merely the opinion that you entertained as to the appearance of the water when you looked at it?

A. With the exception of certain figures under the column in the first table, for instance there is one marked .4. That means then it is a slightly yellow color, and it corresponds to .4. The color is as intense as it would be in a similar column of water containing .4 of a cubic centimeter with a certain solution.

Q. What was that solution?

A. It was a solution which we used for determining the ammonia. It is a mixture of ammonia and double iodide of mercury and potash. Nessler's solution, as made with the Nessler—

Q. And whenever those numbers occur in the other tables, under the head of color the meaning is as you have indicated?

A. It is the determination of the amount of color which was compared with—that is it is a comparative statement of the amount of color, but it was an actual determination.

Q. Did that color have any particular significance in regard to this water?

A. I should say that it had. The color usually shows organic matter, of vegetable origin in the water, but I would not think that the color of the water had any material 8113 significance as to the classification of it from a sanitary standpoint.

Q. In the three columns following under the head of "residue on evaporation" will you please state how those results were obtained?

A. Each sample of water which I received was filtered in part, that is, part of the water was filtered so as to obtain this same sample of water freed from the undissolved matter. Now the residue on evaporation was determined in the unfiltered water and in the filtered water. I obtained this residue by evaporating in each case 100 cubic centimeters of the water to dryness, in a platinum evaporating dish, on a steam bath. After the water had been completely evaporated, the dish was taken from the steam bath and wiped,—that is the bottom of it was wiped to get rid of the water on the outside, and it was then heated for about half an hour at a temperature of about 160 to 170 degrees centigrade; then placed in a dessicator, and cooled and weighed. The increase in weight was the amount of solid matter or residue deposited by 170 cubic centimeters of the water, and from that amount the figure was calculated,—simply a matter of multiplication. The residue dissolved was determined in the same manner, only using the clear filtrate.

That is, it was the water which had had the solids not dis-
8114 solved removed, by simple substraction of the dissolved
residue from the total residue. We obtained in the third column the suspended residue, which gives exactly the amount of solid matter present in the water but not dissolved. That is like clay or sand, little pieces of grass, and one thing and another.

Q. State whether the figures entered in those respective columns correctly indicate the results of your analyses upon each branch of the subject?

A. Yes.

Q. In the next column I see the word "chlorine" heading. State how you ascertained the presence of chlorine in the samples that you examined?

A. In that particular sample, that is the sample from the Illinois and Michigan canal, at Bridgeport, 50 cubic centimeters of the water, or even less, were titrated in a small flask with a solution of silver nitrate, of a certain strength. There had been previously added to this water in the flask one cubic centimeter of a five per cent. solution of potassium chromate. This was added merely as an indicator, to show when the reaction between the chlorine and the silver nitrate was complete. Then this titration was made, as usually made in all cases in that test and this figure is the calculated result of that test.

8115 Q. Do the figures in that column indicate the results of
your analyses for the ascertainment of the presence of chlorine?

A. Yes.

Q. You stated that this water was taken from the Illinois and Michigan canal. Was a different method used in regard to waters taken elsewhere?

A. Where the amount of chlorine was known to be small, or was supposed to be small, a larger amount,—250 cubic centimeters of the water were evaported or concentrated to a bulk of 50 centimeters and then titrated, the idea being that whatever error there might be in this method, is an error which is greater where the amount of chlorine is small, so by concentrating the water and of course the amount of chlorine,—we reduce the amount of the proportion of error.

Q. State whether there are other approved methods of ascertaining chlorine than the one which you used?

A. Yes.

Q. Do you know which of these methods the one you used or other recognized methods, would produce a greater or less degree of chlorine?

A. Personally I think this method will yield a slightly higher amount of chlorine than the gravo-metric method or possibly the Volhard method.

8116 Q. In the next three columns under the head of "Oxygen Consumption" please state what method you adopted in making your analyses of the waters indicated for the purpose of obtaining these results?

A. According to the amount of organic matter in the water, varying amounts of the water under examination were taken, and in each case, the amount was diluted to 100 cubic centimeters. Now for instance, water very rich in organic matter, I might take as low as ten cubic centimeters of the well mixed water and dilute with distilled water to 100, if I didn't think it was heavy enough with organic matter to require that dilution I might take 25, 50 or 100, but if I took less than 100 cubic centimeters I diluted with distilled water, to a volume of 100 cubic centimeters. This definite volume of water was placed in a flat bottomed glass flask and to it we added five cubic centimeters of concentrated pure sulphuric acid, and 10 cubic centimeters of a standard permanganate of potash solution. Then this flask was placed in boiling water so that the level of the water outside of the flask was slightly higher than the level of the water inside the flask. This water on the outside was kept boiling for a period of 30 minutes exactly, if the permanganate of potash should happen to be completely reduced
8117 or nearly reduced in this flask, I would add more so as to keep an excess of permanganate of potash all the time in the glass. When the thirty minutes had expired, the flask was taken from the water and as soon as possible, as soon as I could handle it, the amount of undecomposed permanganate of potash in the flask was determined. From this we could calculate the amount of oxygen which had been consumed by this water in the thirty minutes cooking,—by the water and its contents. The

determinations were made in the unfiltered water, and in the filtered water, then by simple subtraction you found the amount of oxygen consumed by the suspended matter or the undissolved matter in the sample under consideration.

Q. Do the figures stated in those columns indicate correctly the result of your ascertainment?

A. Yes.

Q. Under those heads, first, total dissolved and suspended matter?

A. Yes.

Q. The four columns following, or under the heading, nitrogen as ammonia, please state what methods you pursued in order to ascertain these rules of free ammonia and albuminoid ammonia in the various conditions?

A. The method is the standard method,—in fact
8118 I think now it is the only standard method used for those
various determinations. It was Wanklyn's method, I think,—500 cubic centimeters of the water under examination were placed in an eight or nine hundred cubic centimeter glass flask and five cubic centimeters of the 20 per cent solution of carbonate of soda was added, which simply meant that there was one gramme of carbonate of soda added to the water in the flask. This flask was then connected by means of a glass trap—I don't know the name of it now,—it was simply a trap put in to prevent any of the liquid spattering over into the distilling tube, but it was connected through this glass trap with a block tin condenser. Then it was heated by a gas lamp and boiled at such a rate that 200 cubic centimeters of distillate were collected in one hour. Then this 200 cubic centimeters were mixed thoroughly and an aliquot part was taken for the determination of the free ammonia. The free ammonia was determined only on the original water, the unfiltered water. The albuminoid ammonia was determined in all these samples, after the free ammonia had been distilled. Immediately on completion of the free ammonia distillation the flask was disconnected and 50 cubic centimeters of alkaline permanganate solution were added, to the contents in
the flask and the flask was connected again and again
8119 boiled; boiled at such a rate that 200 cubic centi-
meters of distillate were collected in one hour. Then this

200 cubic centimeters of distillate was mixed and an aliquot part taken for the determination of ammonia. This ammonia, distilled after the addition of the permanganate solution, is known as albuminoid ammonia, and its determination was made on the unfiltered water and on the filtered water both. Then by subtracting the amount in the filtered water, or the amount under the column dissolved, from the amount in the unfiltered water, or the amount in the column "Total," we get the amount of albuminoid ammonia which came from the suspended matter, or the undissolved matter in that water.

Q. How did you ascertain the free ammonia?

A. The free ammonia was ascertained by distilling 200 cubic centimeters of water from 500, after the addition of one gramme of carbonate of soda, and then mixing the distillate and determining the ammonia in an aliquot part of this distillate.

Q. What does sub-column headed "Total nitrogen as albuminoid ammonia" refer to?

A. That is the amount of albuminoid ammonia which was yielded by unfiltered water. The water as it was received by me.

Q. Do the respective figures in those four columns indicate the correct results ascertained by your chemical analyses of the waters indicated?

8120 A. Yes, sir.

Q. The next three columns under the heading "Organic nitrogen" please state how you ascertained those results?

A. A certain amount of the water, 250 cubic centimeters was boiled in, I think, a 500 cubic centimeter Kjeldahl flask,—I am not sure as to the size. It is what we call a Kjeldahl flask, and it was boiled after the addition of one gram of carbonate of soda. This boiling was simply for the purpose of removing all free ammonia and after this had been removed, a certain amount, 25 or 20, I think 25 cubic centimeters of strictly pure sulphuric acid was added to the contents of the flask and then the boiling was continued until all the water had been driven off and until the contents of the flask had become either a very light straw color or clear white. Then after cooling, the flask was rinsed out with water; that is distilled water of course, ammonia free, and an excess of caustic soda added, so that the liquid was alkaline. Then from this alkaline liquid the ammonia was distilled

in the same manner as it was distilled for the water for the determination of free ammonia and albumnioid ammonia. That is, distilled from a glass flask, through one of these glass tubes I spoke of before, and through a block tin condensor, and
8121 from the mixed distillate the amount of ammonia was
determined. This ammonia came from the decomposition of the organic matter in the water under examination and therefore it is called organic nitrogen. It was determined on the unfiltered water and on the filtered water, and from the difference between these two, the figure under the column "suspended" was obtained.

Q. State whether the figures under the column of "total" represent the aggregate of the other two ascertained amounts?

A. Yes, sir, they do.

Q. In the two columns following, under the head of nitrogen as nitrites and nitrates, please state how you ascertained that results?

A. Nitrogen as nitrites was determined by what is known as the Griess method. In this method the clear water is treated with naphthalamine chlorides and sulphanilic acid, and I used hydro-chloric acid. This napthalamine and sulphanilic acid are in an acid solution. Some people use acetic acid and some use hydro-chloric, but I use the hydro-chloric acid. In the presence of nitrites, this re-agent produces gradually a pink color, and the intensity of this pink color is proportional to the amount of nitrogen as nitrites in the water, and the amount of it was determined by comparing the depth of this pink color, or the intensity, with the intensity of the pink color produced un-
8122 der similar conditions, that is, the temperature and time,
when a certain amount of a standard solution of nitrite was tested with this same re-agent. The nitrates were determined by boiling a certain volume of water—200 cubic centimeters I took, and I am not sure as to the amount, I think it was one gram of caustic potash. This boiling was for the purpose of removing all of the ammonia which existed as free ammonia in the water, and which also existed in the rather easily decomposable nitrogenous compounds. Now, after all this ammonia had been boiled off, I usually boiled it down to about one-fifth of the original volume and then I diluted that with cold distilled

water to the original bulk, 200 cubic centimeters, and placed in this water a piece of aluminum wire, pure aluminum wire. The action between the aluminum and the caustic potash which was in the solution still, produced hydrogen, which reduced the nitrites and nitrates to ammonia, and the amount of ammonia after standing until the next day was determined by the same method which I used for determining the ammonia as free ammonia; that is the Nessler determination. Now, from this amount of ammonia which I obtained from the reduction by aluminum, I had to subtract the amount of ammonia which would be produced by the reduction of the amount of nitrites present, then this remainder was the ammonia which was due to the reduction of the nitrate, and that was calculated back to nitrogen and reported as nitrogen.

8123 Q. Having examined the tables to which your attention is called, and which were read in evidence by Dr. Gehrmann, beginning with table 159 and ending with table 196, please state whether the serial numbers placed on each of these tables and the time of collection are correctly entered there from the cards found upon the samples that you received?

A. Yes, sir.

Q. Please state whether under the head of "Examination" the dates there entered correctly state the dates upon which the chemical analyses were begun, to which you referred?

A. Yes, sir.

Q. Now, you will please state whether all the tables to which your attention has been called, contain the correct results of the chemical analyses made by you on the dates indicated in these tables?

A. Yes, sir, they do.

Q. And state also whether the appearance of the water is correctly indicated in all the tables to which your attention has been called?

A. Yes, sir. Of course you understand under the head of "turbidity" and "sediment" that those are just simply comparative. It is no determination. It is just my judgment
8124 at that time, but the sediment as made there is the way I put them down at the time.

MR. JEFFRIES: I move to strike out all the testimony of this witness for the reason that it has no bearing upon the issues involved in this case, and the testimony that has reference to the taking of samples and the analyses of samples of water taken, prior to the chemical analyses of the water made prior to the opening of the drainage canal and that he has not testified to any analyses having been made by him of that water, subsequent to the opening of the drainage canal.

I move to strike out his testimony for the further reason that the defendants have shown that it is impossible to determine from chemical analyses the sanitary condition of the water for domestic and drinking purposes, and for the further reason that the defendants have shown that certain living organisms exist in the water so analyzed, the character and nature of which organisms they are unable to determine, and that from a chemical standpoint they are unable to determine whether they be disease producing organisms or non-disease producing organisms,
so that all of such testimony has no probative force in the
8125 determination of the issues involved in this case.

JUDGE SPRINGER: I move to strike out all of this objection as stated with reference to what the defendants have proven in this case, as merely a comment upon the evidence.

CROSS-EXAMINATION, by Mr. Jeffries.

Q. You testified as to table 159?

A. Yes, sir.

Q. Your analyses contained on table 179 were made in the same manner as that of 159?

A. Yes, sir.

Q. And along at the same time?

A. Yes, sir, a few days difference, during different parts of the week, but that is all.

Q. How did you make the test for the sediment?

A. Why, it was no test, it was just simply the relative amounts that I judged present. That notation was always made before the sample was stirred up and I judged the relative amount, whether there was a very small amount or a medium amount or a very large amount, whatever it might be, of matter which had already settled to the bottom.

Q. Does it appear on the bottom of the table?

A. Yes.

8126 Q. By ocular observation?

A. That was all.

Q. Now, if that sediment had been of the same color of the water, would you have been able to detect it?

A. Yes, you could see whether there was any sediment on the bottom of the bottle or not.

Q. If the sediment had been as transparent as the water would you have been able to detect it?

A. No, I would not.

Q. If there had been living organisms existing in the water, swimming around in the water, capable of motility, were motile, would you have been able to detect them with the naked eye?

A. No, sir.

Q. Now, to determine the turbidity of the water you disturbed the sand at the bottom, didn't you?

A. No, I judged the turbidity. I would rather use the word "judged" than determined, because it was simply an estimation; that was all; it was my judgment.

Q. And that estimation might be of a different result as made and determined by different persons?

A. Oh, yes, but as I was going to say, this judging of the turbidity was done before the sample had been stirred up. It was the relative amount of suspended matter, undissolved
8127 matter which had not settled to the bottom during the shipment.

Q. Now, if there had been deposited in one of these bottles a number of disease producing organisms or germs, and in another bottle of the same character of water, no germs had been deposited, would those germs have any effect on the turbidity of the water?

A. I don't think they would.

Q. In other words, it might have been a living mass of germs?

A. Yes, sir.

Q. And yet have no effect so far as the turbidity is concerned?

A. I don't think it would have made any perceptible difference.

Q. So that the question of turbidity does not determine the presence or absence of living organisms that produce or do not produce disease?

A. Not in itself, no, sir.

Q. Does it in any way add to the determination of whether or not there are such germs or organisms present?

A. No, it has nothing to do with the question of presence or absence of micro-organisms.

Q. Couldn't the water be very turbid indeed and yet not 8128 contain a single germ that would produce disease of any character?

A. It might be produced that way, yes, sir.

Q. And upon the other hand, as you stated before, it might contain many such germs, and yet not have any effect upon the turbidity of the water?

A. Yes, it might.

Q. So then the turbidity of the water would not be considered of any value, would it, in the determination alone; that is the turbidity alone would be of no value in determining the presence or absence of organisms?

A. Not the turbidity alone.

Q. Now, then, of what value would it be in determining the condition of the water in connection with any other chemical constituent, or analysis or operations through which a water is put to determine its sanitary condition?

A. Well, it will have an effect when you consider the entire result; that is the result of all the tests which are made.

Q. I will ask you if it is not a fact that samples of water may contain large quantities of the various chemical substances that we find in it, which would be considered by chemists as rendering water unpotable or unfit for sanitary use, objectionable to the chemist in the laboratory, and at the same time, 8129 that the sample of water would not contain a single disease producing organisms?

A. Yes, we might find that kind of water.

Q. And at the same time you might find a very small quantity of each and all of the various constituents, chemical elements in the water, and yet it would be a living mass of disease producing organisms?

A. I don't know that I would want to state that.

Q. If it was a living mass of disease producing organisms, could you detect it in your chemical analyses?

A. It would not be a living mass of organisms of any kind unless there was at least a certain amount of organic matter for them to live upon and you could detect that.

Q. But the organic matter may be present with the disease producing germs absent, may it not?

A. Yes, sir.

Q. Do you reason that the disease producing germs could not be present unless the organic matter was there?

A. Unless the organic matter was there. They could be present but would not live.

Q. So, then, the idea is, the more organic matter, of whatsoever character contained in any water, the more dangerous it is for domestic purposes, is that it?

8130 A. The more apt we are to mark it suspicious, or call it unpotable water.

JUDGE SPRINGER: I move to strike out of the record all questions put to this witness and all answers made by him in reference to the presence or absence of bacteria or pathogenic germs in water, this witness not having qualified as a bacteriologist. I haven't asked the witness a question in bacteriology.

MR. JEFFRIES: I have referred in my examination thus far, of the witness, to living organisms contained in the water, whether they be bacterial germs or organisms of some other character.

JUDGE SPRINGER: Chemistry has nothing to do with living organisms.

MR. JEFFRIES: I accept the admission of counsel that chemistry has nothing to do with living organisms and knows nothing about it.

Q. Now, then, going back to this living mass of organisms, or mass of living organisms, let us dilute those organisms and say it contains a large number of living organisms of disease-producing character, would it necessarily show in the turbidity of the water?

A. No, not necessarily.

8131 Q. Now, would they be shown by any other portion of your chemical analysis of that water?

A. No, there is nothing in the chemical analysis that would show that.

Q. Now, under the head of Residue on Evaporation in table 171 I find you have a column of totals, what does that mean?

A. Those figures give the number of parts of solid matter contained in 1,000,000 parts of the water under examination in each case.

Q. Then there is dissolved parts, what does that mean?

A. That is the number of parts of solid matter, of dry matter contained in one million parts of filtered water, so that, take for instance, the first one, 306, and 313, comparing the two, the water as it was received by me contained 313 parts per million of dry matter, or solid residue, but the clear water contained only 306. That is of the 313 parts, 306 were dissolved in the water, while seven were not dissolved.

Q. Now, was it dissolved in water as the water then existed, or did you dissolve it?

A. I simply took the water as it came; I didn't do anything with it, except to filter it.

Q. The seven parts were suspended matter?

A. Yes, sir.

8132 Q. What was the character of that suspended matter and what may the character of suspended matter in water be?

A. As a matter of fact I made no examination of that suspended matter to tell what it was.

Q. It might be germs of anthrax spores?

A. Well, I am inclined to think that anything as small as that would go through the filter paper, possibly it would not, but part of it would.

Q. Then you do not know whether you took all the solids in suspension out or not, do you?

A. Well, I do not think I did take all bacteria out.

Q. Where did it go to if you did not take all of it out in suspension?

A. It went through the filter paper.

Q. The solids in suspension, so-called?

A. Yes, the solids in suspension.

Q. But if they were living organisms of sufficient minuteness to pass through the filter paper, then you did not get it in the suspended matter, did you?

A. No, sir.

Q. And if they were of sufficient size to be kept in the filter, you did get them in the solids in suspension?

A. In the suspended solids, yes.

8133 Q. Now, then, what treatment did you put that total suspended matter through after that?

A. I didn't do anything with it.

Q. You don't know what its character was?

A. No.

Q. It might have been spores of disease producing character, and it might not?

A. Yes, sir.

Q. Is it not a fact that you find that the total solids in suspension of the water examined at Grafton in 1899, was from five to six times as much during December to what it was during the month of July that year, November and December?

A. In November the amount was very much higher than it was in July, five or six times.

Q. I will ask you if the sample examined on the 7th day of July and the 13th day of July was not seven parts per million of suspended matter?

A. Yes, sir.

Q. And that the sample examined on the 20th of July was 16 parts per million?

A. Yes, sir.

8134 Q. And the sample examined on the 27th of July was 18 parts per million?

A. Yes, sir.

Q. Now, I will ask you if the sample examined on the 3rd day of November was not 94 parts per million?

A. Yes, sir.

Q. And the sample examined on the 10th day of November, 27 parts per million?

A. Yes, sir.

Q. And the sample on the 16th of November, 48 parts per million?

A. Yes, sir.

Q. And the sample on the 23rd of November, 85 parts per million?

A. Yes, sir.

Q. So that there was a greater amount of suspended matter during the month of November than there was during the month of July?

A. Yes, sir.

Adjourned until 2:00 p. m., same day.

8135 2:00 p. m., Monday, October 12th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

D. B. BISBEE,

resumed the stand for further cross-examination by Mr. Jeffries, and testified as follows:

Q. What did you say you meant by the residue on evaporation?

A. The amount of dried matter left by the evaporation of the water under consideration, expressed in parts per million.

Q. Both as to the dissolved matter and the suspended matter?

A. Yes, as to the dissolved solids and the suspended solids.

Q. Now, how did you obtain those determinations?

A. A definite volume of the water was evaporated to dryness in a weighed platinum dish, placed on a steam bath so that the heating agent was live steam, and after the water had been entirely evaporated from the contents of the dish, apparently so, at least, the dish was placed in an air bath and heated for about half an hour at a temperature from 160 to 170 centi-
8136 grade. Then the dish was cooled in a dessicator and weighed and the increase in weight is the amount of residue referred to.

Q. Now, that is the way you have changed it,—the dissolved?

A. Well, the dissolved, yes, and the total increase. You understand the figure for total is the figure.

Q. Well, the total is the dissolved and suspended added?

A. Yes, but I obtained the suspended by subtracting the dissolved from the total. The suspended is not a direct determination.

Q. Well, now, is that an accurate determination?

A. Yes, sir. Just as accurate as any work that I can do.

Q. If the water should be permitted to stand in the sun until evaporation had taken place, would you have the same results?

A. Yes, if the sample, if the dish after having been dried in the sun was exposed to that heat of 160 or 170 degrees. I would not want to say that I would have the same results without that. Of course it is pre-supposed that dirt or stuff from the air will not flow in in either case.

Q. Now, did you ever examine the contents of these samples by a microscope ?

A. No, sir, I made no such examination.

Q. Never discovered any living organisms in them?

8137 A. Not at all.

Q. You know they were there, though, don't you?

A. From what I was told. I didn't know it from any personal knowledge.

Q. What system did you say you used in obtaining the chlorine test?

A. I don't remember the name of it. I titrated a certain volume of the water with silver nitrate, using chromate of potash as the indicator, to show that the re-action was complete.

Q. Now, you spoke of one plan being more accurate than another. You mean by that that a certain part of the chlorine would escape from the tests?

A. No.

Q. In other words, you said that one system would produce a larger quantity of chlorine than another?

A. Slightly higher, I said.

Q. One method, then, will produce a slightly higher amount than another?

A. Yes, I think so.

Q. Now, will any system exactly obtain and accurately obtain the exact amount of chlorine in any sample of water?

A. Yes, sir, I think so. I think the Gravo-metric method

8138 will give the closest results, and give results which are within the limits of errors, as we say.

Q. You have got to figure on some errors, have you not?

A. There is a certain amount of error that is alowed in all technical work.

Q. Where did you say you got these samples of water that you used?

A. They were delivered to me by the various express companies.

Q. Were they shipped to you?

A. Shipped to the city laboratory. That was the way they were addressed.

Q. The health department?

A. Yes, sir.

Q. How soon after you received them before the examinations were made?

A. Well, the examination for nitrites was started at once, just as soon as I could get at it, and the notations as to turbidity, sediment, color and odor were made on the spot at once. The other tests were usually started within a few hours—the free ammonia was started within a few hours of the time they were received.

Q. Would the exposure to the light and the hot, warm temperature of the room for any length of time have any 8139 effect upon the results so far as the dissolved and suspended solids were concerned?

A. I don't think they would. That is of course, you understand if exposed a day or two. I would not want to make that statement with regard to any indefinite time.

Q. You don't know whether some chemical changes would be going on in that bottle, that would be in the river?

A. No, I would not want to say that it would be the same.

Q. Your idea is, however, that there would not be much change in a day or two?

A. Very little in the amount of the solids.

Q. Then there would be very little change in the water of the river from day to day, would there not?

A. The change in that particular,—the change would be very slight in water,—the exact duplicate of that; that is the water flowing down would not change very much.

Q. The chemical constituents of the water then would remain practically the same from day to day?

A. Aside from sedimentation, and with slow processes of oxidation.

Q. You are of opinion that a day or so in the samples exposed to the various temperatures,—changing temperatures, would have but slight effect upon the water?

8140 A. On the solids. Are you referring to the solids now?

Q. The solids.

A. Referring to the solids, the difference of a day or two in the time of determining them would make very little difference.

Q. Well, now, what effect would it have on any of the chemical constituents? Is there any chemical constituent that you have obtained from these analyses that would be affected?

A. Why, yes.

Q. By the sample remaining in the bottle for a day or so, exposed to a warmer temperature or a colder temperature, as the case may be?

A. The ammonias and the nitrates and nitrites in a natural water are generally in a state of change all the time, so that even a day's difference in time of analysis of two exactly similar samples might show a decided difference in those elements.

Q. In other words, there might be more nitrites by reason of the water standing?

A. There might be more and might be less. I don't know just which.

Q. Then if these nitrites are to be considered in any way as affecting the sanitary condition of the water, you must consider the time that it has stood in the bottle before it has been analyzed, must you not, or do you know?

8141 A. I would rather answer that in a different way. I would rather say this, that if I was going to use the determination of nitrites as any basis at all for the determination of the sanitary condition of the water, I would want to make the nitrites immediately on the samples being taken.

Q. Then it would not be a safe proposition to use the nitrites as any element of the sanitary condition of the water in the river when they had been obtained from the examination after it had remained in the bottle for a day or so?

A. Well, I would consider them—

Q. Well, now, isn't it a fact?

A. Oh, I could not place as much credence in my opinion as if I had made that test right on the spot, at the time the sample was taken.

Q. Isn't it a fact that the chemical analyses, where samples are taken and shipped with a varying temperature, do not disclose the actual chemical conditions of the water in the river at the place the samples were taken and at the time the samples were taken?

A. I don't think there would be very much difference in anything except the nitrites and nitrates and the free ammonia.

Q. Then we come down to the proposition that the water is
practically in the same condition from day to day, if we
8142 don't consider the nitrites or nitrates to any great extent,
upon the sanitary condition of the water, and they are the
only things that do change, then the water is naturally about
in the same condition from day to day, is it not?

JUDGE SPRINGER: He didn't state that. He stated a day or two,—not continuously.

Q. MR. JEFFRIES: Well, for a day or two, then there was practically no change in the water?

A. Well, I said a very slight change, except from sedimentation and from a very slow oxidation.

Q. Did you take any of these samples yourself?

A. No, sir.

Q. You don't know how long they had been on the road?

A. Only from the marks made on the collectors' tag. That is the only means I have of knowing anything about that.

JUDGE SPRINGER: What time of the day would they be received?

A. At all times. I have had them come in after five o'clock at night.

MR. JEFFRIES: Were there any times when there was some delay in the shipment of the sample or in the analysis, after it had been received in the laboratory of the city health department?

A. Yes, there was an occasional time when they were,—
when the analysis was started, say the second day after
8143 they were taken. Sometimes it would result from their
not being delivered promptly; sometimes the train late,
something like that.

Q. And examined as much as the third day after they were delivered?

A. I don't remember that.

Q. Take sample 553, on table 179—sample collected August 21, and analysis was made August 24th?

A. Yes, there was a big delay.

Q. Would you think that there was any considerable change in the condition of the water while it remained in the bottle those three days?

A. Yes, I should think that the nitrites might be materially different from what they were when taken, and that the free ammonia might be a little bit different, but not as much. Of course you will understand there will be a great deal slower changes in the bottle than there would be in the open air, because there would be no gases escaping or nothing of that kind in the bottle. Whatever was in the bottle would stay there.

Q. The septic operation would be better then wouldn't it?

A. Well, I don't know as I would want to say that. The
bottles were never completely full. There was always a
8144 little bit of air in the top of the bottle.

Q. Wouldn't the temperature have a great deal to do with it?

A. With the rapidity of bacterial action, yes, the formation of the nitrites.

Q. Doesn't that condition cause chemically change?

A. In the formation of nitrites, yes—the conversion of nitrogen compound into nitrites and nitrates.

Q. Then to that extent these samples did not correctly portray the actual chemical condition of the water at the time these were taken?

A. At the time the samples were taken, yes—these as I said would be true to whatever extent there might have been a change in the amount of nitrates or nitrites, or free ammonia. Otherwise I think the analysis would show their condition, or should show their condition.

Q. Where did the free ammonia come from if not from the albuminoid ammonia?

A. Well it would possibly come from the destruction of albuminoid ammonia.

Q. Well then, it would affect the free ammonia to some extent wouldn't it, or the albuminoid ammonia, I mean?

A. Well, I don't think the albuminoid ammonia would be affected very much by a day or two.

8145 Q. Well, would the free ammonia be affected?

A. It might be affected to a slight extent.

Q. Well, then, free ammonia is affected and albuminoid ammonia is not affected, and free ammonia comes from albuminoid ammonia. How do you reconcile those statements?

A. The free ammonia would be the one that would change. That is, for instance, if the ammonias are oxidized.

Q. They would change into albuminoid ammonia?

A. Into nitrites.

Q. Go into nitrates and nitrites?

A. No, because they would result in increased nitrates for instance, and decreased free ammonia.

Q. Are those nitrates included in the free ammonia?

A. No.

Q. In the albuminoid ammonia?

A. No, in neither one.

Q. They form no part of it?

A. They are not included at all in that.

Q. How did you obtain the exact amount of free ammonia and albuminoid ammonia in the sample of water and at the same time obtain nitrites and the nitrates in that sample of water?

A. The nitrates and nitrites were done by an entirely different method on a different specimen of water. That is,
8146 a different part of that same sample.

Q. And that might cause a variation, might it not, by not being able to obtain the exact nitrates that are in the particular sample of water that you examined for the purpose of ascertaining the amount of ammonia?

A. There would be no difference there because the samples were all mixed every time before any determination was made, so that they would be parallel.

Q. Then they run parallel, do they?

A. That is you have the same samples right straight through from the time they started.

Q. Well, unless the total solids were properly diffused in the water they would not run parallel, would they?

A. Oh no, certainly not. Not necessarily.

RE-DIRECT-EXAMINATION, by Mr. Springer.

Q. If the time of the delay between the taking of the sample and the analysis affected the results, that effect would be shown would it not by comparing the ascertainments of the sample of that day with the previous or succeeding day, when the delay was less?

MR. JEFFRIES: I suggest now, under the testimony of
8147 this witness himself there could be no comparison drawn
between the samples of the various days, or the analyses that were made on the various days, because they were taken at least a week apart and although they may have been taken at the same exact spot in the river, the conditions in that river were changed so that the same chemical constituents were not found in one sample that were found in all the other samples, so that not any two samples are comparable.

Q. (Question repeated).

A. No, I would not want to say that at all, because I understood you to mean comparing the results obtained, for instance today with the results of the sample taken yesterday or the sample taken tomorrow.

Q. Yes.

A. Well, unless we could know that these two or three different samples taken on different days would have the identical composition,—we could not make any comparison between them.

Q. You could not compare them?

A. No. What I meant to say was, you would have to have the assurance that these samples taken the different days or at different times, were exactly the same.

MR. JEFFRIES: Chemical constituents?

A. Chemical constituents present in them. If they had
8148 exactly the same, why then you could compare the figures,
but unless you know them you cannot compare them.

JUDGE SPRINGER: You could only make comparison then by holding the same sample over?

A. Yes, holding it over another day and then make a comparison.

Q. Those samples show some difference I suppose?

A. Yes, they will show some difference in the water.

D. B. BISBEE.

8149 **ARTHUR W. PALMER,**

called as a witness in behalf of the defendants, being first duly sworn by the Commissioner, was examined in chief by Judge Springer and testified as follows:—

Q. You may state your name, residence and occupation?

A. Arthur W. Palmer, Champaign, Illinois; Professor of chemistry in the University of Illinois.

Q. How long have you held that position?

A. Fourteen years.

Q. Where were you educated?

A. In the public schools of Illinois; at the University of Illinois, at Harvard; at Berlin and Goettingen in Germany.

Q. What course did you take in the University of Illinois?

A. I took the course in chemistry.

Q. How long?

A. Four years. From 1879 to 1883.

Q. What at Harvard?

A. Two years in chemistry, from 1884 to 1886.

Q. And what courses in Germany at the colleges?

A. Chemistry still, at Berlin and Goettingen, in 1888 and 1889.

8150 Q. Have you made any further study at schools with reference to chemistry?

A. Well, I have been instructor in chemistry for—

Q. I had reference to being as a student only?

A. No, not as a student, except that we are always students.

Q. Now state what experience you have had as an instructor in chemistry?

A. As an assistant for a year in 1883 and 1884, as an instructor in the years 1886, 1887 and 1888, that is two years and during the last fourteen years as Professor of chemistry in the State University.

Q. What are your duties in the University as Professor of chemistry?

A. To teach chemistry.

Q. Do you teach practical analyses of water?

A. I do.

Q. You haven't made a specialty of bacteriology I believe?

A. I have not.

Q. Has the subject of chemical analysis and analyses of water been considered practically and to any considerable extent in your course of instructions?

A. It has.

Q. Have you personally engaged in making chemical analyses.

8151 A. I have.

Q. During how many years?

A. About 22 years as a student and as investigator.

Q. What degrees have you taken if any, in colleges?

A. I took the degree of Batchelor of Science in Chemistry at the University of Illinois in 1883; the degree of Doctor of Science in Chemistry at Harvard in 1886.

Q. Any other?

A. That is all.

Q. State whether you had any conferences with Professor Jordan of the University of Chicago at any time in reference to making certain examinations and analyses of the waters of the Illinois and Michigan canal, and the Sanitary canal, the Desplaines and Illinois and other rivers?

A. I did.

Q. When were those conferences held?

A. At various times beginning in March, 1899, if I remember the month right (after referring to book). Yes, in March.

Q. State what agreement you and Professor Jordan reached in regard to making chemical analyses and bacteriological examinations of the waters to which I have referred?

8152 A. Well, the conference in March, 1899, included a number of other individuals besides Professor Jordan and myself and at that conference it was decided that samples of water should be taken at various points along the Illinois river, the Mississippi river, the Missouri river at one point, and from the Illinois and Michigan canal. Also from some of the tributary streams of the Illinois; and that samples should be taken from each point selected, once a week, and that the number of samples taken at each point simultaneously should be sufficient to send one set of said samples to Professor Jordan at the University of Chicago; one set to Dr. Gehrmann, at the municipal laboratory, Chicago, and one sent to me at the University of Illinois.

MR. JEFFRIES: I object to the witness stating anything about conferences being held and I object to any questions upon that proposition as incompetent, irrelevant and immaterial. The witness should be confined to what was done and not with reference to what was agreed upon.

JUDGE SPRINGER: The things that were done will be shown hereafter. The conferences to which reference has been made have been referred to for the purpose of showing that a concerted effort was made to make on three parallel lines certain investigations, and that this is one of the lines which
8153 was pursued?

Q. State who selected the persons who were to take the samples of water and the places at which they were to be taken?

A. Professor Jordan and I jointly selected the points and selected the persons who were to make the collections of the samples.

Q. State how you made these selections of persons and places.

A. We went to different points along the different streams mentioned just before—visited them, noted local conditions, pointed out the spot where a sample which should be most representative of the conditions in the river in that vicinity could be obtained. We selected men to make the collections by reason of their availability and their apparent fitness for doing the work.

Q. What instructions orally, if any, did you give to them and directions as to taking samples?

A. We showed them the spot at which the sample was to be taken and tried to impress upon them the fact of the importance of always getting the sample at that same spot. We showed them how to collect the sample by demonstrating, by collecting samples ourselves in their presence, showing them how to do the work.

8154 Q. Did you cause any blanks or certificates to be furnished to these collectors?

A. We did.

Q. What were those certificates to contain?

A. They were to contain the dates, name of the place where the collection was made, and such matters as temperature of the water, temperature of the air, height of water in the river, the direction of the prevailing winds, the rainfall and so on, passage of vessels, and other things. They are given here; I am not sure that I remember all these points, but they are stated here in the copy that is printed in our report.

Q. Was there anything printed on the back of these certificates?

A. There was.

Q. What was it?

A. Directions as to the collecting, the packing and the shipping of the samples.

One of the certificates known as defendants' Exhibit No. 11 for identification, used for this purpose having been shown to the witness, he identified it as being the blank furnished.

8155 THE WITNESS: I identify that as one of the certificates so prepared and used.

Q. And the instructions on the back?

A. I do. These are instructions that we prepared and placed upon the certificates for the guidance of the collector.

Q. I wish you would state please the points at which these samples were to be taken and your reasons for selecting those points?

A. The first point was at Bridgeport, a short distance below the pumping station, which conveys water or sewage from the south fork of the south branch of the Chicago river into the old or Illinois and Michigan canal. The reason for taking the sample at this point was to show the condition of the discharges which at that time and for many years before, had been pumped into the old canal and sent thence into the Desplaines river at Lockport and Joliet and so on down into the Illinois river.

Q. And after the drainage canal was opened, what other points in this vicinity were selected?

A. After the opening of the drainage canal samples of water were taken every week at Bridgeport, the Kedzie Avenue crossing, for the purpose of showing the condition of the more dilute discharges which from that time on were sent down
8156 into the Desplaines and thence into the Illinois through this new channel.

Q. State who was selected at that point to take the samples?

A. Mr. Joseph Weis took samples at this point.

Q. What was the next place selected?

A. The next point was Lockport. Here a sample was taken from the Illinois and Michigan canal for the purpose of showing what if any changes had taken place during the flow from Bridgeport, about 29 miles away, and particularly for the purpose of showing the character of the sewage and water discharged from this channel into the Desplaines river, this being the point of discharge into the natural valley of the Desplaines.

Q. Now in the next period, in 1900, did you take any other samples at Lockport from the drainage canal?

A. Well we did throughout, both in 1899 and 1900, take samples at Lockport and also from the Desplaines river. At first the samples taken in the Desplaines river showed the natural, or unnatural as it may be,—condition of that stream just above—just above the point at which the Chicago sewage was discharged. After the opening of the sanitary canal, the conditions were greatly changed just at the point where the collections in the Desplaines river had been made, and after that
8157 time inasmuch as the natural discharge of the Desplaines river above this point was small, as compared with the combined discharges of the Illinois and Michigan canal, and the new Sanitary canal, the collection of samples from this somewhat comparatively insignificant tributary, was discontinued.

Q. Who was your collector at these three places?

A. The collector at these three places was Mr. O'Brien.

Q. An expressman?

A. Yes, he has been a stationary engineer I believe there, but was an express agent at the time he was doing most of this work.

Q. Now what other place in the Desplaines river did you select and for what reason?

A. The point at Joliet just above the town, a point in the basin, where the Illinois and Michigan canal crosses the Desplaines river, as it from that point on passes down along the west bank or just at this point, what is the north bank of the Desplaines river. The reason for making the collection at this point was to determine the condition of the combined mixture of Chicago sewage discharged at first through the Illinois and Michigan canal, and subsequently through it and the new drainage canal. The mixture of the liquids from these two
8158 sources with the water from the upper Desplaines.

Q. Before the opening of the canal where was this old canal water received at this point?

A. The old canal discharged in part at Lockport, and in part where the canal joins and crosses the river at Joliet, four miles below, but the entire discharge of Chicago sewage is effected by the time we reach this point. A large part of it takes place at Lockport nearly four miles above, but the final emptying of the canal occurs at this point, Joliet, so that this is the first point where we get the complete effect of the discharge of Chicago sewage into the Desplaines valley.

Q. That is, by the Illinois and Michigan canal, you mean?

A. By the Illinois and Michigan canal, yes and since the opening of the drainage channel the entire effect of its discharge also.

Q. What was the average flow of the Illinois and Michigan canal at this place?

A. The average flow for many years preceding 1900 was from 35,000 to 36,000 cubic feet per minute. This being the amount pumped into the canal at Bridgeport. The flow at times at Lockport would exceed this amount because of the discharge of various ditches along the line of the canal and the surface wash, and sometimes too, from the overflow of the Desplaines river into the canal, but the quantity pumped from the

8159 Chicago River into the canal is indicated by the figure I have given, 35,000 to 36,000 cubic feet per minute. Since the opening of the sanitary canal, the pumping into the old canal has been greatly reduced in volume and in time. In 1900 the pumping was continuous throughout the year, but the quantity pumped was much less, averaging 26,700 cubic feet per minute during the year. In 1901 pumping occurred only during the navigation season, which lasted practically from the beginning of May to the end of November, or until well in November. It continued seven months only. During this time an average of 23,000 cubic feet per minute was raised by the pumps at Bridgeport. The average, if calculated for the entire year being about 13,800 cubic feet per minute, but it is to be noted that the pumping continued only seven months, and that at the rate given above, namely 23,000 cubic feet—

Q. Was the rate during the time that the pumps were actually in operation?

A. That the pumps were actually in operation.

Q. Did you select any other place on the Desplaines river for taking samples, and if so, for what reason?

A. Samples were also taken at a point just below Joliet. The purpose was to note what effect was caused by the discharge of the sewage of Joliet into the Desplaines river,
8160 but as it proved that in the dry summer season there was no flow in the Desplaines river below Joliet, the entire flow at that time being carried by the canal and distributed along into the river at various points along the 66 miles of its course between Joliet and its terminus at LaSalle or Peru, the collection of samples in the stream, or bed, rather, in the bed of the Desplaines below Joliet was discontinued and for a time the collections were made in the canal just below Joliet.

Q. Who made these collections at Joliet?

A. At Joliet the collections were made by Mr. Raymond Hurd.

Q. What place did you select in the Kankakee river, if any, and for what reason?

A. The point upon the Kankakee river that was selected for collection of samples was Wilmington, a point near to the mouth of the river and where it was believed the samples would show the general character of the water of the Kankakee river, as it was about to be discharged into the upper end of the Illinois,—that is, to mix with the discharge of the Desplaines river and by confluence with the latter, to form the Illinois river.

Q. The confluence of the Kankakee and the Desplaines rivers forms what is known as the Illinois river?

A. Yes sir.

8161 Q. Which is the larger stream of the two forming the Illinois?

A. Ordinarily the Kankakee river is the larger. It is much more uniform in flow, though at times the upper Desplaines may discharge as much water for short periods as the Kankakee does. Take it the year through, the discharge of the latter far exceeds the discharge of the Desplaines.

Q. How far did you say above the mouth of the Kankakee was it that you had the samples taken?

A. Why, it is about fifteen miles. I cannot say exactly, the twists and turns of the river.

Q. Was it below or above Wilmington?

A. The sample?

Q. Yes?

A. Right at Wilmington.

Q. Above the town or below the town?

A. Why the samples were taken near the dam there, which I believe is right in the town. I cannot state positively. This place Wilmington is the one point that I did not personally visit. Professor Jordan visited Wilmington and selected the spot there, and he can give you more specific information as to the precise point, but by correspondence I understood that the sample was taken right close to the dam.

Q. Has that town a sewerage system if you know?

8162 A. I think not.

Q. Who made the collections there?

A. The express agent made the collections at Wilmington, Mr. R. P. Elliott.

Q. What was the next point which you established for the taking of samples?

MR. JEFFRIES: We move to strike out all the testimony of this witness with reference to the analyses of samples of water taken from the tributaries of the Illinois river, and object to the witness testifying further in reference to samples taken and examined from the tributaries of that river for the reasons heretofore stated at the time previous witnesses were examined in reference thereto.

Q. JUDGE SPRINGER: Proceed now with regard to Morris.

A. The next point was upon the Illinois river, the town of Morris, situated between nine and ten miles below the junction of the Kankakee and the Desplaines, a point at which the dilution of the Chicago sewage and the Desplaines river water with the Kankakee river water may to some extent be determined. At this point in the very dry season the flow before the opening of the drainage channel, might at times consist mainly of the sewage discharged from Chicago, but there was always 8163 slight dilution at this point, because the Kankãkee river never went entirely dry, as do some of the other streams of the state. In fact the Kankakee might be regarded as really the upper section of the Illinois, because it is the only feeder with the exception of Chicago, that never goes entirely dry.

Q. Who made the collections at this place?

A. Mr. J. W. Miller collected at this point.

Q. Where was the next point selected and for what reason?

A. The next point was the Fox river at Ottawa. The Fox river next to the Kankakee ordinarily serves as the chief supply of the waters of the upper Illinois. The sample was taken at a short distance above the aqueduct which carries the Illinois and Michigan canal across the Fox river, and the purpose was to note the character of the water of this tributary with a view to studying its effect upon the waters flowing in the Illinois river channel.

Q. Did you ascertain the area drained by the Fox river?

A. Yes, it is stated here, 2,697 square miles.

Q. How does that compare with the area drained by the Kankakee river?

A. It is about half of it. The latter is something over 5,000 square miles.

8164 Q. What sewage, if any, is received by the Fox river?

A. It receives the sewage of a number of manufacturing towns all along its course, among which, Elgin and Aurora are the largest. It included also the discharge of a large amount of nitrogenous organic matters at Geneva, where there is a large glucose works.

Q. How far is Geneva above the mouth of the Fox river?

A. If I remember rightly, it is about 45 miles above the mouth of the Fox river. I cannot be positive, but we can look it up and easily correct it. Somewhere in the neighborhood of 45 miles, possibly a little more.

Q. What was the next place selected, and what was the reason for making the selection there?

A. The next point?

Q. Yes?

A. The Illinois river at Ottawa. The purpose was to determine the condition of the water at this point just before the Fox river water enters, and to note what change if any, took place during the flow of the mixture of the Illinois river from Morris to Ottawa.

Q. How far was that?

8165 A. This is 33 miles below the junction of the two streams, and about 23 miles below Morris, the town at which the last sample from the Illinois river was taken. That is, the one last mentioned.

Q. Whom did you select to make these collections?

A. Mr. Lester Horan made the collections at Ottawa, both from the Fox river and from the Illinois river.

Q. What was the next place selected?

A. The next place was LaSalle, and at LaSalle, several samples were taken, one from the Big Vermillion river, which is a somewhat considerable tributary entering from the left bank as you go towards the mouth.

Q. How large an area does that drain?

A. About 1400 square miles. But it is extremely variable in the volumes of water discharged, like nearly all other Illinois rivers in that respect. In the freshet season it carries a comparatively great volume of water. In the dry season it may go almost entirely dry.

Q. What important towns in Illinois are situated on the banks of this river above its mouth?

A. The towns of Streator, and Pontiac, are the most important on this stream. Their sewage is emptied into the river;
they get their water supply from the river and in dry
8166 weather they pump all the water out of the river and
after passing it through themselves and their households,
they send it back into the river.

Q. Where was the other point that you selected?

A. Then the Illinois river at LaSalle. Sample taken at the wagon bridge, which is about three miles below the mouth of the Big Vermillion river. I should have stated that the sample collected from the Big Vermillion river was taken at a point about half a mile within its mouth. The sample from the Illinois river at LaSalle taken beside the wagon bridge, three miles below the mouth of the Big Vermillion. The purpose was to determine the condition of the water in the Illinois river at this point, and to note particularly too, what changes, if any, took place during the flow from Ottawa to LaSalle.

Q. How far was that—what was that distance between those two towns?

A. Well, that is about 25 miles. I have got it here in the table somewhere. I cannot always keep these in my mind. Fifteen miles from Ottawa to LaSalle. I came near giving that wrong. Then another sample was taken from the Illinois and Michigan canal at LaSalle. The water in the Illinois and Michigan canal is diluted at various points between Joliet and La-
Salle, by the introduction of water from various sources.
8167 On the other hand, at different points along this stretch
it discharges into the Illinois, and then, too, it is itself
polluted by discharges of sewage from various towns, into the canal. The analysis made at LaSalle was for the purpose of showing the condition of the water in the old canal just as it was about to discharge finally at the lower end of the canal into the Illinois river.

Q. Do you know the length of that canal from Bridgeport to this point?

A. The canal is about 100 miles long,—99 and some large fraction.

Q. And this is practically the mouth of the canal is it, this place?

A. Yes, at LaSalle or rather Peru,—the two towns are contigous,—the canal just passes LaSalle. They always speak of it as ending at LaSalle, but the real end where the canal rejoins the river, or first joins the Illinois river is at Peru, about three miles below LaSalle. The last locks are at LaSalle, but there is a continuation down the river to Peru.

Q. Who was selected for the purpose of making these collections?

A. Dr. William Frazer of the town of LaSalle.

8168 Q. Where was the next point selected?

A. The next point was upon the Illinois river at Henry, where there is a dam across the stream.

Q. Did you visit that dam?

A. Yes sir.

Q. State what kind of a dam it is?

A. So far as I can tell, it is an excellent dam, a large one for the purpose of aiding navigation in the Illinois river, provided with locks to facilitate such use, and furnshed, if I may use the term, with a lock-keeper who is on duty to look after the dam and lock. The purpose of making the collection at Henry was to note again the changes which took place between the next preceding point of collection and this,—changes occurring in the waters of the Illinois river, and due to natural processes, and a contribution of LaSalle's and Peru's sewage to the Illinois river, which contribution takes place just below the point at which the LaSalle samples were collected.

Q. State the nature of that sewage from Peru and LaSalle?

A. Well, it includes house sewage, manufacturing wastes from zinc works,—the largest in the world are there at Peru—I should say first, the largest in the world are at LaSalle and the next largest in the world are at Peru, and discharges from both of them go into the river. Then there are fertilizer works
8169 there, cement works, and coal mines and others, and wastes of all sorts from these various industries, as well as the house sewage from these towns is discharged into the river just below LaSalle and Peru.

Q. Do you know the distance between Peru and Henry?

A. It is about thirty miles,—the distance from LaSalle to Henry,—33 miles.

Q. Who made these collections for you at Henry?

A. It was the lock-keeper, Mr. McCune, and the samples were taken just above the dam.

Q. Where was the next place selected?

A. The next place was at the Narrows, about three miles above the Court House at Peoria. The name of the immediate locality being called Averyville. It might be called a suburb of Peoria. The sample was taken at the bridge across the Narrows at this point.

Q. How far is it from Henry to this point, if you know?

A. It is about thirty miles again--yes, it is just 30 miles from Henry.

Q. And how far from Lockport, the mouth of the drainage canal?

A. About 130 miles.

Q. Who collected these samples for you at Averyville?

8170 A. They were collected by employes of the Peoria waterworks, under the general direction of the superintendent of the Peoria waterworks, Mr. Dabney H. Maury. They were collected by Mr. Robert Martin, and by others who had been designated by Mr. Maury, and who have testified here.

Q. Where was the next point selected?

A. The next point at which collections were taken was Wesley City, three miles below the Court House at Peoria, about six miles below the point at Averyville. The reason for making the collections at this point was to determine the influence of Peoria sewage upon the waters of the Illinois river, for the reason that enormous discharges in the aggregate, of household sewage and wastes from various manufacturing industries take place just above Wesley City.

Q. Is there a creek near there?

A. Just below the town of Peoria, Kickapoo Creek discharges into the Illinois river, and it also conveys some industrial wastes into the stream of the Illinois.

Q. State in what part of the river the samples at this place were to be taken?

A. The instructions to our collectors were that the samples at Wesley City should be taken at mid-stream, at a point almost opposite the railway station at Wesley City.

Q. Did you select the exact point in the river?

8171 A. Yes.

Q. And point this out to the water taker?

A. I did.

Q. Where was the next place that you selected?

A. The next point was the Illinois river at Pekin. The reason for taking the sample at Pekin was that at Pekin again there are enormous discharges of refuse matters from distilleries and other industries, as well as a portion of the house sewage of the town. The sample was collected at the point in the river a short distance below the point at which the final discharge of refuse matters at Pekin occurs.

Q. How far is Pekin from Peoria?

A. It is about fifteen miles,—twelve to fifteen. The river men always give various different figures.

MR. JEFFRIES: It is three miles further by water than it is by land?

A. Always, yes. From Peoria—well, it is about twelve miles, from twelve to fifteen. People give it variously. I have been along both ways several times, but I never carried a pedometer.

Q. Was this point at Pekin selected as the place below the sewers of that city?

A. It was.

8172 Q. And below the wastes of the distilleries, etc?

A. It was.

Q. Who made these collections at Pekin and Wesley City?

A. Mr. D. H. Jansen, county surveyor, and an engineer.

Q. Where was the next point which you selected?

A. The next point was just above the town of Havana, on the Illinois river. The collection was made a short distance above the mouth of the Spoon river, which is a considerable tributary entering on the right bank of the Illinois. The purpose in making the collection at this point being to determine the effect of the flow for a distance of about thirty miles, 33 miles from Pekin to Havana, to see what effect occurred upon the refuse matters introduced into the stream at Peoria and Pekin, 33 and 45 miles respectively, above this point.

Q. Who took these samples at this place?

A. The samples at Havana were taken by Mr. H. G. Heberling.

Q. Were any samples taken from the Sangamon river?

A. Samples were taken from the Sangamon river at Chandlerville.

Q. What is the drainage area of the Sangamon river?

A. About 5,600 square miles.

8173 Q. Any towns upon that stream?

A. The towns of Decatur and Springfield discharge their sewage into the Sangamon river, or into small tributaries of the Sangamon, which in the case of Springfield, soon finds its way into the Sangamon river.

MR. JEFFRIES: I move to strike out the answer of the witness and all testimony with reference to the drainage area of the tributaries of the Illinois river unless it be supplemented with the entire drainage area of the Illinois river valley.

JUDGE SPRINGER: We will put that all in.

Q. Did you make a collection at this point opposite Chandlerville?

A. I did.

Q. Who made this collection there?

A. Mr. E. O. Spink made the collections at Chandlerville.

Q. What other points on the Illinois river?

A. The town of Beardstown, 31 miles below Havana was the next point. The collection was taken near the C., B. & Q. bridge.

Q. Was this above or below the mouth of the Sangamon?

A. Below the mouth of the Sangamon, the purpose being to discover what changes took place in the waters of the Illinois while flowing from Havana to Beardstown and the effect of the introduction of the Sangamon river water, which occurs between these two points. 8174

Q. Who made these collections?

A. The collections were made by Mr. G. W. Barneycastle, under the supervision of Mr. J. A. Carney, engineer of the C., B. & Q. railway.

Q. What other place was selected on the Illinois river?

A. The point at Kampsville, just above the dam, 30 or 31 miles above the mouth of the river and about 57 miles below

Beardstown. The point was to note the changes which took place in the Illinois river water in its flow from Beardstown, 57 miles above, down to this point, which is near the mouth of the stream.

Q. What is there at Kampsville that is notable, in the stream?

A. There is the United States Government dam there which is under the charge of a United States engineer, who is permanently in residence there and who has charge of the improvements along the lower Illinois river. The water at this point in the Illinois river is ordinarily unaffected by changes in the height of the water in the Mississippi river, but at times when the water is high in the Mississippi the flow at this point is retarded and at times even the water may back up as far as this in the Illinois river. The collection at 8175 this point was made by Mr. C. V. Brainard, the assistant United States engineer in charge of the dam.

Q. Were any samples taken at Grafton at the mouth of the river and if so state what was done there?

A. At the mouth of the river at Grafton samples were taken at a point about two miles within the mouth of the Illinois river, a point at which ordinarily none of the water of the Mississippi river affects the Illinois, or rather at which Mississippi river water does not ordinarily mix with the Illinois river water. Samples at this point were collected by Mr. B. F. Robinson.

Q. Did you take any samples from the Mississippi river at this point or above the mouth of the Illinois?

A. We did. Mr. B. F. Robinson again collected the samples from the Mississippi river at a point in mid-channel about two miles above the town of Grafton, and where the water of the Illinois river does not mix with the Mississippi river water.

Q. Do you know what the relative volume of flow of the two rivers is at this point?

A. Well, it varies greatly at different seasons. Sometimes the Mississippi is high and the Illinois is low; sometimes the Illinois is high and the Mississippi is low. Sometimes they are both low together and at other times they are both high 8176 together, but taking the mean for the year through, and the flow in the Mississippi river in the year 1899, was about five times or a little more than five times the flow in the Illinois river.

MR. JEFFRIES: I object to the witness testifying as to the relative stream flow of the Illinois and Mississippi rivers, for the reason that he has not disclosed the source and means of his information.

MR. TODD: In reply to the objection will state that if counsel wants to know the source and means of his information, that will be afforded him on cross-examination.

A. The measurements were made by United States engineers about the year 1882, at the mouth of the Illinois river and at Hannibal in the Mississippi river. The results of their measurements are stated in various reports, including that by Mr. Leverette upon the Water Resources of Illinois. Measurements of the flow in the Illinois river have been made at Kampsville, where the flow, as measured, constitutes ordinarily practically all of the flow of the Illinois river at Grafton, and so indicates the volume of water discharged into the Mississippi at the mouth at Grafton.

MR. JEFFRIES: Now I move to strike out the answer of
the witness for the reason that it does not state the rep-
8177 resentative conditions that have existed since the open-
ing of the Chicago drainage canal and the answer of the
witness discloses the fact that it is based on conditions that existed long years before the opening of the canal.

JUDGE SPRINGER: I will ask you now if you have made any estimate of the comparative flow of these two streams for the year 1900, after the drainage canal was opened?

A. I have.

Q. What was it?

A. For 1900 the flow of the Illinois amounted to about 22.6 parts as compared with 77.4 for the upper Mississippi. These determinations being made from the determinations of the proportions of chlorine contained in the Illinois river water, and a comparison with the proportions of chlorine contained in the upper Mississippi river water and in the water of the Mississippi river below the mouth of the Illinois, where partial mixing of the two streams had occurred.

Q. Were any points selected below this where samples were taken, if so, state what?

A. At Alton about 17 miles below Grafton, samples of water were taken from the Mississippi river at five points across the stream, opposite the new pumping station of the Alton city waterworks. The five different points across the stream
8178 being selected as the points of collection, for the purpose of determining, if possible, what degree, or in what degree, the mixing of the Illinois river water with the upper Mississippi river water had taken place at the time the two streams had joined at Grafton, and progressed in their course, to this point, 16 miles below. The samples at Alton were taken by Mr. George Brooks.

Q. Were any samples taken at the mouth of the Missouri river at the place called West Alton?

A. Samples were taken from the Missouri river at a point a short distance within its mouth at the crossing of the C., B. & Q. bridge, known as Fort Bellefontaine, but near to the hamlet of West Alton.

Q. West Alton being on the north bank?

A. And Fort Bellefontaine I suppose on the south bank, though I could not find the fort.

Q. Who took these samples?

A. The samples at this point were taken by Mr. James Matthews.

Q. And do these samples represent the Missouri river water before the mixing takes place with the Mississippi?

A. They do.

Q. What was the next point on the Mississippi river?

8179 A. It was the chain of rocks, which we called Mitchell, since I couldn't find anyone to collect the samples for us there, except a prominent farmer named Henry Atkins, who who lived on the Illinois side, and whose post office is at Mitchell, several miles away from his house.

Q. Just explain, will you, what was done at this place, as it is an important point?

A. At this point four samples of water were collected.

Q. You mean each time?

A. Yes sir. Each day a collection was made, four sets of samples were taken at four different points across the stream, one being towards the Missouri shore about 400 yards, sometimes they say 400 feet—but supposed to be in the middle of the stream as it flows down to the intake tower of the Missouri shore. The next sample was taken immediately beside the intake tower of the St. Louis waterworks. The third sample at this point, or the third set of samples at this point were collected at mid-channel, which is possibly midway between the inlet tower and the Illinois shore, and the next sample, the fourth at this point, was collected toward the Illinois shore, about 400 yards from the land.

Q. Yards or feet?

A. Well, it varied somewhat; at certain times in the year the water spread farther across, and if you got the point
8180 as located in the bed of the river, it was farther away from the shore when the water was away up.

Q. What was the object of taking the samples at the various points in the stream at this place?

A. The object of taking the samples at these four different points was to note the character of the water at the different points across the stream. To note and determine if possible what amount of mixing of the three streams, the Illinois the Mississippi and the Missouri had taken place by the time this body of waters reached the intake or the point opposite the intake tower of the St. Louis waterworks.

Q. Where was the next point selected for taking samples?

A. The next point selected was a tap in St. Louis, the sample was taken by Mr. Emil A. Lapelle, but when he left the country, the samples were taken by Mr. August Johnson, the latter doing most of the work.

Q. Were there any other points on the Mississippi river selected?

A. Samples were taken at cross-section points in the Mississippi river at Jefferson Barracks, about nine miles below the center of the town, the purpose being to note what amount of mixing of these various waters had occurred by the time they reached this point, and in a secondary manner to see what effect the St. Louis sewage had upon the lower Missis-
8181 sippi, although the latter was perhaps a sentimental part

and no such continuous or thorough study of the conditions below the chain of rocks was made, as was made at and above the chain of rocks, along the streams that we have been considering.

Q. Now I believe you stated that you saw these collectors in person?

A. Yes sir.

Q. What instructions or directions did you give them in regard to the manner of immersing the bottles into the river and of taking the samples of water, and at what part of the stream they were to take their samples?

A. With the exception of the various cross-section points to which I have referred the collectors were directed to make the collections at the middle of the channel and they were told to immerse the bottle with the stopper in place, to a depth of a foot below the surface, then to remove the stopper allowing the water to enter until the bottle was nearly full, then to replace the stopper, withdraw the bottle and immediately tie it up and tag, pack and ship by the earliest and most direct route.

Q. And to rinse the bottle?

A. In some of the collections they were directed to rinse the bottle first with some of the water of the river, yes sir.

Q. Who prepared the bottles and how were they prepared?

8182 A. In the various laboratories they of course were prepared by the different people looking after the work. In my own laboratory we all looked after it. I looked after part of it and some of my assistants were helping. The bottles were cleaned out by means of a mixture of dilute sulphuric acid and bichromate of potash, then rinsed thoroughly with distilled ammonia free water, and drained and tied up securely with a piece of sheet rubber over the stopper and so prepared for the chemical samples.

Q. Were they sterilized?

A. Not for the chemical samples, no sir, except as the treatment with these agents might effect that perhaps.

Q. How about the smaller bottles?

A. The smaller bottles were sterilized.

Q. What were they used for?

A. They were for the bacterial samples.

Q. Were they prepared in your laboratory?

A. No, not in general. Professor Burrill, who made the bacteriological examinations at our place, looked after the shipping and preparation of the bottles for the bacterial samples, but they were sent over to us and packed with our chemical bottle.

8183 Q. How were they to be shipped, in what manner?

A. Shipped in wooden cases and packed in excelsior. The bacterial samples were packed in ice, the chemical samples were not.

Q. Who received these samples at your laboratroy?

A. I received them myself, with my assistants.

Q. When a sample was received, what did you do?

A. The first thing was to place a number upon the tag which was upon the bottle, a serial number, and to enter that number in our record. Then the tag number was placed also upon the certificate which was inside of it. A number placed upon the bottle itself, upon the outside tag, and upon the certificate which accompanied the sample.

Q. What else as to the analyses?

A. Then the analysis was begun immediately, particularly the determination of such constituents as are susceptible readily to change?

Q. What were those?

A. The nitrites, the nitrates in particular, and steps were taken to get the free ammonia determinations under way at once. The other determinations, particularly the total solids and chlorine, were ordinarily not started until after these
8184 determinations I have mentioned were under way, for
the reason that the substances mentioned are not so liable to change as are the nitrites, nitrates and free ammonia. Of course the determination of albuminoid ammonia, which accompanies that, or rather immediately follows the determination of free ammonia was started when the free ammonia determination was started.

Q. Was the turbidity of the water entered of record?

A. After numbering the bottles and tags and certificates of course a note was taken of the physical appearance of the

water, the turbidity, the amount of sediment there might be in the bottom of the bottle and in a general way the odor. The sample, before any of it was poured out for analysis, was thoroughly shaken, in order that such matters as had deposited upon the bottom of the bottle during transit, could be shaken up and intimately mixed with the sample of water. Then the samples were poured out for the various determinations, care being exercised to keep such matters as were shaken up, in the water, in suspension during the time that the various portions of the given sample were being measured out for the different determinations. At the same time too, notice was taken of the odor, if any, by bringing the mouth of the bottle containing the water, into near proximity with the nostrils and sometimes a sample of water was heated in order to note
8185 whether any odor was developed or made more pronounced by warming the water.

Q. How did you note the odor?

A. We simply made a record of the report brought by one's nostrils as to the possession by the sample of a fishy, gassy, or any other odor that we could recognize and distinguish by any of the ordinary terms, musty, as sewage, gassy, as when the discharges of gas works, liquor, gas into the water; fishy perhaps in some cases, or odorless, in case we failed to detect any particular odor.

Q. Did you note the color of the water?

A. Yes sir.

Q. For what purpose and in what way?

A. The determination of color was made by comparison with the color developed by the Nessler solution, such as is customary in the determination of free ammonia. This seemed the most feasible means of noting and recording the color, in the case of these waters, since the natural color of the water was more nearly comparable to that produced by the Nessler reagent than to any other substance we were familiar with. And in the determination of color usually it was necessary to filter the water because the waters of most of these streams at nearly all times, is too turbid to admit of even an approximate determination of the color, unless the floating matters
8186 be removed.

Q. What kind of tubes were used for this purpose?

A. The Nessler tube, made especially of a colorless glass, rather thin, about ten inches in length, about eight inches high to the mark which indicates the measured volume of 50 cubic centimeters.

Q. Did you make any analyses for the purpose of determining total solids and if so how did you reach that determination?

A. We did. Total solids were determined by evaporating 250 cubic centimeters of the water, after adding two hundredths of one gram of sodium carbonate, the addition of the sodium carbonate being made by measuring in five cubic centimeters of a four-tenths per cent. solution into a sample of 250 cubic centimeters of the water. The dish with the contents being placed upon a water bath until the water was substantially all evaporated and then being transferred to an air bath where it was heated at 180 degrees centigrade until practically all of the water was removed from the residue. It ordinarly taking an hour for this purpose.

Q. Did you determine the loss on ignition?

A. We determined the loss on ignition by treating the residue of evaporation, after it had been heated in the oven as above indicated, by heating the dish and its contents to a dull redness over a Bunsen lamp. The dish and residue being suspended within a larger platinum dish, the latter being kept at redness by the direct application of the flame of the Bunsen lamp mentioned above. 8187

Q. What method did you employ for the purpose of determining the presence of chlorine?

A. The method for the determination of chlorine was the ordinary standard method by titration with silver nitrite solution, using, potassium chromate as indicated. The quantity of chromate used was in all cases one cubic centimeter of a five per cent solution. The end point of a reaction was in all cases determined by comparison with the color of a blank. The quantity employed for the purpose was in many cases fifty cubic centimeters of the original sample, but in cases where it was known or suspected that the contents of contained chlorine, that is the chlorine was small, a larger quantity was employed for the purpose, 250 to 500 centimeters of the original sample accurately measured, was treated with sodium carbonate, five cubic centimeters of the solution of four tenths per cent strength being employed, and the mixture was evaporated so far that a sample of fifty cubic centimeters should be obtained for the tiration with silver nitrate as indicated above.

Q. Did you make any analyses for the purpose of determining the amount of oxygen consumed?

8188 A. I did.

Q. Please state what it was?

A. The determination of oxygen consumed was made by a slight modification of the standard method, that is digestion with potassium per manganate in acidified condition; a hundred cubic centimeters of the water were used for the purpose. To this quantity of sample 2 cubic centimeters of pure concentrated sulphuric acid were added. Then ten cubic centimeters of the standard permanganate solution were run in and the mixture heated within a flask which was immersed in the boiling water of a bath and kept so immersed, and the water kept boiling for thirty minutes. At the end of this time, if the color of permanganate was apparent the samples were removed from the bath and a measured quantity of oxalic solution was added. The excess of oxalic acid titrated with the same permanganate solution, and the difference between the quantity of oxalic acid solution and the permanganate solution employed in these several portions, indicated the quantity of oxygen taken by the organic matters from the permanganate, and hence indicated as oxygen consumed. In a good many cases the organic matters in the waters consumed more oxygen than could be furnished by the ten cubic centimeters of potassium permanganate employed. In such cases another sample of the water was taken, 8189 heated as indicated above, with the exception that twenty, that is double the quantity of permanganate was directly added to the water, the rest of the process following substantially as indicated above.

Q. Did you determine the presence of nitrogen as free or saline ammonia?

A. I did, for this purpose 250 cubic centimeters of the water sample were diluted to 500 cubic centimeters with the nitrogen free distilled water. Five cubic centimeters of a twenty per cent sodium carbonate solution were added, and the liquid distilled in a round bottomed 900 cubic centimeter Jena glass flask over a naked Bunsen flame. The flasks supported upon asbestos rings, were conneeted with the condensor by means of a modified form of Reitmair and Stutzen distillation bulbs. That is the modification made by Hopkins. The condensor is used where half inch or three-quarter inch block tin tubes, which pass through a tank of cold water. The length of the tube exposed to the cooling influence of the water being about 20 to 22 inches. During the latter part of the investigation, tubes of somewhat thinner aluminum were employed for the purpose. As nearly all of the waters which we had to examine in the course of these investigations, were high in free ammonia, comparatively. We made the collection by distillation into two hundred cubic centimeter flasks, instead of collecting in separate lots of 50 C. C. in Nessler tubes, and subsequently the determination of the quantity of free ammonia was made by thoroughly mixing the contents of the flask and taking out an aliquot portion for the Nesslerization. The samples being allowed to stand at the temperature of the room, until the temperature should adjust itself to that of the room, so that the standards used in the Nesslerization should be of the same temperature as the distillates from the water samples which were being investigated. 8190

Q. What determination did you make for the purpose of determining the presence of the albuminiod ammonia?

A. The albuminoid ammonia was determined by the ordinary standard method by use of the residue remaining from the distillation of the free ammonia. After this determination the distillation was stopped, the flask disconnected from the condensor, 50 cubic centimeters of alkaline permanganate solution—the ordinary standard solution employed for the purpose was introduced. The flask immediately connected again with the still and the distillation proceeded with at the same rate as for the distillation of the free ammonia, that is at about the rate of 200 cubic centimeters per hour until 200 cubic centimeters of distillate was obtained, which then was used for the determination of the nitrogen as albuminoid ammonia 8191 in ways similar to that indicated above, for the determination of the nitrogen as free ammonia, namely by Nesslerization.

MR. JEFFRIES: I move to strike out all the testimony of this witness with reference to the manner in which the various chemical constituents of the water were obtained, for the reason that no connection is shown between these chemical constituents so ascertained from the samples, and the sanitary condition of the water at the places the samples were taken.

ADJOURNED until 10:00 A. M. Tuesday, October 13, 1903.

8192 10:00 A. M., Tuesday, October 13th, 1903.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ARTHUR W. PALMER,

resumed the stand for further direct-examination by Judge Springer and testified as follows:

Q. Professor, you have used the term "Nesslerization" in defining the methods you employed in obtaining certain results. Will you please state what you mean to convey by that term,—what Nesslerization is?

A. Nesslerization is the determination of free ammonia in solution by means of the so-called Nessler reagent, a solution of iodide of mercury in iodide of potassium with caustic potash present. When free ammonia in solution is brought into contact with this reagent a color develops, varying from the faintest yellow to a dark reddish yellow, according to the quantity of ammonia in the liquid. The process goes by the name of Nesslerization, and is a standard method in chemistry, especially for water analyses. In our work care was taken that the distillates in which the free ammonia from the samples 8193 of river water obtained as indicated above, was to be determined, were of the same temperature as the standards which were mixed up with known quantities of ammonia for the purpose of making comparison, and thereby determining the quantity of ammonia in the distillate, and so in the original water sample. Ammonium chloride solution used for making up these comparison standards was of such strength that one cubic centimeter contained ammonium chloride corresponding to .01 of a milligram of nitrogen. The eighteen standard mixtures made for the purpose of comparison, contained quantities of the standard ammonium chloride solution, as follows:

.05 of a cubic centimeter; .01, .2, .4, .6, .8, 1., 1.2, 1.4, 1.6, 1.8, 2., 2.5, 3., 3.5, 4., 4.5, and 5. cubic centimeters.

In Nesslerizing, one cubic centimeter of the Nessler solution was added to the contents of each Nessler tube, and the mixture allowed to stand twenty minutes for the development of the full color, because the full color does not develop instantaneously upon making the mixture, nor within fifteen to twenty minutes or more of the time of mixing. The reagent was always added to the samples, that is, the distillate from these samples, and the standard mixtures simultaneously, for the purpose of giving the same time for the development
8194 of the tint in the sample and in the standard with which
it was to be compared, and the readings were all taken within one hour of the time that the mixing occurred. That is within one hour of the time that the Nessler solution was added to the various samples and standards. For facilitating an accurate comparison of the tints a special camera which cuts out all side lights was employed, the camera being arranged with mirrors for the purpose of sending northern sky light up throughout the length of the tube, and reflecting to the eye an image of the cross section of the tube. The light having been passed through an eight inch column of the liquid before being so reflected to the eye. The same method of Nesslerization applied to the determination of the nitrogen as free ammonia, and to the determination of the nitrogen as albuminoid ammonia.

Q What method did you employ for the purpose of determining the total organic nitrogen?

A. The total organic nitrogen was determined by the method of Kjel Dahl. For this purpose 250 cubic centimeters of the water were diluted with 250 cubic centimeters of nitrogen free distilled water. Then five cubic centimeters of a twenty per cent sodium carbonate solution which would contain one gram of potassium carbonate, was added to the mixture,
8195 and this final mixture subjected to distillation for the re-

moval of all free ammonia, the distillation being conducted in the same manner and pushed to precisely the same point as that reached in the distilling over of free ammonia, in the determination of the free or saline ammonia. After the removal of the free ammonia as indicated, ten or twenty cubic centimeters of pure nitrogen free sulphuric acid were added and the solutions heated under the proper precautions, until the water was all expelled, and the organic matters completely destroyed. After cooling the resulting liquid, 250 cubic centimeters of ammonia free, distilled water were added, and then an excess, usually about 50 cubic centimeters, of strong nitrogen free sodium hydroxide solution was added. The flask was immediately connected with the condenser. The contents of the flask mixed by thorough shaking, and the distillation which was conducted at first very slowly was continued until 200 cubic centimeters were distilled over into the 200 cubic centimeter flask. The contents of this flask were then mixed thoroughly and an aliquot portion of the distillate so obtained and mixed was employed for Nesslerization in the ordinary manner. And from the result of the Nesslerization comparison, the quantities of nitrogen existing in the water in organic combination were determined.

8196 Q. What method was employed by you for the purpose of determining the presence of nitrogen as nitrites?

A. Nitrogen as nitrites were determined by the ordinary standard method, as follows:

50 cubic centimeters of the water were placed in the Nessler tube, one cubic centimeter of an acid solution of napthalamine hydro chloride, the solution being of strength as follows: Eight grams of the napthalamine, eight cubic centimeters of strong hydro-chloric acid, with sufficient water to make up one liter of solution. The other solution employed was the hydro-chloric acid solution, containing five per cent of strong hydrochloric acid, and as much sulphanilic acid as the mixture of hydrochloric acid and water, which was added to make up a liter, would hold in solution.

The test with the sample was made by adding one cubic centimeter of each of the above solutions, to the 50 cubic centimeters which had been placed in the Nessler tube, and the mixture so made was allowed to stand for an hour in order that the development of the full tint might have time to take place. Sim-

ultaneously with the addition of the reagents to the water sample which was being examined, the same quantities of the reagents were added to a series of solutions which contained accurately known quantities of pure sodium nitrite. If a color ap-
8197 peared in the water sample in the course of twenty min-
utes to one hour after the addition of the reagents, it was matched with some one of the tints developed in the series of standards, and the quantity of nitrite contained in the original water was recorded, as being the same as that contained in the standard mixture which produced the same tint. If no color developed in the course of an hour, the water was regarded free of nitrites.

Many of the river waters examined contained so much nitrite that the color developed in the undiluted sample was too deep for accurate comparison. In such cases quantities of from 1 to 10 cubic centimeters of the sample were diluted to 50 cubic centimeters with nitrogen free distilled water, before adding the reagents. Waters which were turbid, or deeply colored, were clarified and decolorized by treatment with aluminum hydroxide and filtration, before making the test for nitrites. The comparison of tints was made in the camera, and in the tubes which were used for Nesslerizing. The standard solution of sodium nitrite employed was prepared from pure silver nitrite by reaction with sodium chloride, and for convenience in making up the standards, was made in two strengths, one solution containing in each cubic centimeter the equivalent of .005 of a milligram of nitrogen; the other contained .0005 of a milligram of nitrogen.

8198 Q. What method did you employ for the purpose of determining the presence of nitrogen as nitrates?

A. I determined nitrogen as nitrates by the usual aluminum reduction method. For the purpose, 100 cubic centimeters of the water were treated with two cubic centimeters of nitrogen free sodium hydroxide solution of 33 per cent strength. The solution was then boiled down rapidly to about one-third its volume in order to remove the free ammonia. The liquid was then diluted to 100 cubic centimeters with nitrogen free distilled water. It was cooled and put into a large test tube. Then one gram of aluminium in the form of a strip of comparatively thin foil was introduced and the tube with its contents was placed in a water bath, the temperature of which was kept at about

25 degrees centigrade (78.2 Fahrenheit) where it was allowed to remain over night. The reductions to ammonia were ordinarily complete when the examinations were continued next morning. The contents of the reduction tube, including such portion of aluminum foil as remained intact were transferred to a distillation flask, 250 cubic centimeters of nitrogen free distilled water being used to wash out the tube and dilute the liquid. The distillation of the free ammonia thus produced by the reduction of the nitrates was conducted precisely as for the determination of free or saline ammonia. In all the various samples of river water which were examined, determinations
8199
were made of the total solids and loss on ignition of free ammonia and albuminoid ammonia, the total organic nitrogen and of oxygen consumed, and the other determinations as hereinbefore set forth,—to use a legal term,—but a number of these determinations were made not only upon the original sample, but upon a filtered portion of the original sample, for the purpose of distinguishing between matters in suspension and those in solution,—these total solids were determined not merely in the original water, which contained much matter in suspension, but also in a filtered sample of the same, and the suspended solids were thus indirectly determined, as the difference between the total solids in the original sample and the total solids obtained by the method given above, in the filtered sample. Filtered portions were used also for the determination of albuminoid ammonia in solution. The total organic nitrogen in solution, and for the oxygen consumed by the matters in solution. The differences between the results thus obtained in the filtered samples and the figures obtained upon the original whole or unfiltered samples being due to matters in suspension.

Q. What method did you employ for the purpose of determining dissolved oxygen in the samples of water analyzed by you? 8200

A. Dissolved oxygen we determined chiefly by the method of Albert Levy—if that is the way the Frenchmen pronounce his name—though some determinations were made by the Winkler method, mainly for purposes of comparison with the Levy method. The Levy method was used for the reason that we found it more convenient. It is as follows:

A special pipette with a glass cock at each end, attached to the cock at one end being a funnel tube, the capacity of the apparatus between the two stop-cocks being 107 cubic centimeters, was filled with the water sample to be examined, by immersion in the river, when the determination was made on the spot; by drawing the water up into the pipette when the determination was made at the laboratory. The pipette was filled with water between the two cocks; then two cubic centimeters of the caustic alkali solution which is described below, were introduced by placing it in the funnel at the top and by so manipulating the two stop cocks that the caustic alkali solution was allowed to run down and mix with the water sample without introducing any air. The funnel was then rinsed out and five cubic centimeters of the ammonia ferrous sulphate, the solution described below, were introduced first into the funnel and then into the pipette, by the same manip-
8201 ulation as indicated above. The water which ran out of the pipette at the bottom as the reagents were admitted at the top was caught in a beaker in which the subsequent titration with potassium permanganate was to be effected, and which already contained two cubic centimeters of a fifty per cent solution of sulphuric acid. It is assumed that the alkali and the iron solution in entering the pipette displace their own volume of water, and with careful manipulation this is undoubtedly essentially effected, so that we may assume that within the pipette there remains 100 cubic centimeters of the original water sample, together with the seven cubic centimeters of the reagents. The mixing of the liquids within the pipette was effected by shaking the pipette with an eccentric rotary motion. In the course of a few minutes the action is completed, and from the color of the precipitate one may gather an idea as to the relative amount of oxygen contained in solution in the water. That is, if the water is about saturated the precipitate is apt to show a somewhat brownish color, due to the formation of ferric hydroxide, while if the quantity of oxygen is very small the precipitate is likely to be black, owing to the preponderance of ferrous hydroxide in the precipitate. After a few minutes, when

the action appears to be complete—five cubic centimeters 8202 of sulphuric acid are introduced into the funnel, the cock between the funnel and the pipette being open, the cock at the bottom of the apparatus remaining closed; the sulphuric acid by reason of its greater gravity passes down from the funnel through the orifice in the stop-cock, into the interior of the vessel and mixing with the liquid, dissolves the hydroxides of iron, rendering the entire liquid acid, and yielding a clear solution. When this action is complete as shown by the perfect clearing up of the solution, the contents of the pipette are run into the beaker and the excess of ferrous salt remaining unaffected by the dissolved oxygen in the original sample, is determined by titration with the standard potassium permanganate solution. A blank test is run upon 107 cubic centimeters of the original water for every determination that is made, this being easily accomplished while the reactions within the pipette are taking place. In running the blank, 107 cubic centimeters of the original water sample are measured into a beaker. Then seven cubic centimeters of the sulphuric acid are added and the liquid mixed. After this the caustic potash, two cubic centimeters in quantity is added, and finally, precisely five cubic centimeters of the ammonio-ferrous sulphate solution is added.

After mixing, titration of this solution by means of the 8203 potassium permanganate solution is effected, precisely as in the actual determination as indicated above. The difference between the two sets of readings, that is the figures obtained for the blank test and those obtained from the direct determination, represents the quantity of dissolved oxygen in 100 cubic centimeters of the water.

Q. State whether the Albert Levy method is more convenient than that used by Winkler?

A. In our practice we found it more convenient to use the Levy method rather than the Winkler method, because of the necessity of running a blank on every sample of water examined. Because of the organic matters and other matters in these river waters, which were the subject of the present examination, it was essential that a blank for correction be run upon every sample. That blank can be much more easily and quickly made for the Levy method than for the Winkler method.

Q. Please state whether you made the oxygen determinations on the spot or otherwise?

A. A considerable number of the determinations were made on the spot, but it was not practicable to make all of them so, and consequently a large number were made upon samples which were especially collected for the purpose and were shipped to the laboratory.

8204 Q. How long after the taking of the sample was it until you made your determinations in the laboratory?

A. Ordinarily they were made at the laboratory within 24 hours. In some cases, a few cases, comparatively, the samples were longer in transit, and the determinations were not made for 48 hours after the time of collection of the sample.

Q. Do the waters of the Illinois and Mississippi rivers contain great amounts of organic matter?

A. They do. We found it possible to prevent the consumption of the dissolved oxygen during the time that the samples were in transit between the points of collection and the laboratory by adding mercuric chloride to the original sample, but the determinations were rendered somewhat more difficult in consequence of this addition, although it was found possible to make the determinations so, and the comparison of determinations made on the spot with samples shipped to the laboratory after treatment with mercuic chloride, showed that under these conditions there was practically no loss of the dissolved oxygen during the time required for transportation.

Q. Did you make any comparisons with the Winkler method of making these determinations?

A. Yes, and we found that ordinarily the differences between the results given by the two methods were not
8205 great. They are indicated in the tables which will be considered later. I referred to the solutions used in the method. The reagents employed consist of a solution of 150 grams of caustic potash in a liter of water, a solution of 22 grams of ammonio-ferrous sulphate in a liter of water. A solution of sulphuric acid containing fifty per cent of sulphuric acid by volume, and a standard solution of potassium permanganate of such strength that one cubic centimeter, is exactly equivalent to .1 of a milligram of oxygen.

Q. State how many different determinations you made from these various analyses to which you have referred?

A. What various analyses?

Q. The ones that you have just described?

A. Oh yes. In the sanitary chemical analyses, there have been fourteen quantitative determinations made upon each sample of water.

Q. That is, parts per million you mean by that, do you?

A. Well, determination of quantities yes, and the results of these appear in tables No. 1 to 80, and in tables, A. B. C, D, respectively, and in tables 95a, 95b, 95c, 95d, 95e, 95f and 95g, respectively.

Q. You have stated that the results of these analyses about which you have been testifying were set forth in 8206 certain tables which were numbered from 1 to 80. I hand you certain tables, and ask you to look at these and state whether the results of the chemical analyses made by you during the time indicated, and of the samples of water indicated, taken at the different points about which you have testified here are set forth in the tables which I have just placed in your hands, numbered from 1 to 80 inclusive?

A. I identify the tables which you have just placed in my hands, as the ones to which I but a moment ago referred as incorporating the results of the various analyses of the samples of river waters which are the subject of the present investigation.

Q. Were these results entered by you in your office and under your supervision?

A. They were.

Q. And do they contain a correct statement of the determinations which are indicated in the tables, respectively?

A. They do.

Q. Were these various results reached in the manner that you have indicated in your testimony heretofore?

A. They were.

Q. You may now, professor, read the tables indicated, in evidence in this case?

8207 MR. JEFFRIES: To the reading of which said tables into the record complainant objects because no proper foundation has been laid for their introduction or their reading.

Complainant further objects for the reason that according to the explanation given by this witness and all other witnesses who have been produced by defendants, they are unable to give any connection between the analyses of the samples of water taken from the Illinois river, the drainage canal, and the Chicago river, and the sanitary condition of the water in the river.

Complainant objects for the further reason that this witness has not qualified as a sanitarian or a pathologist, and for the further reason that there is nothing in the tables which shows the presence or absence of disease producing organisms, and for the further reason that defendants have proved that that is beyond the power of the science of chemistry to determine, the sanitary condition of water for domestic and drinking purposes.

Complainant objects for the further reason that the samples of water were not taken with reference to all conditions of the river so far as temperature and the seasons of the year are concerned, and the manner of taking was not such that the results of the analyses based thereon are comparable with 8208 each other, or that the results are in any way comparable with the conditions actually existing in the river at any time, and at all times.

JUDGE SPRINGER: I move to strike out this objection for the following reasons: First, the question as to whether a proper foundation has been laid for the introduction of this evidence, is one for the Court to determine—

MR. JEFFRIES: I addressed my objection to the Court.

JUDGE SPRINGER: And it is therefore referred to the court for that purpose, and it is not a part of the testimony in this case. Secondly, I desire to move to strike it out for the reason that counsel has assumed to summarize the testimony which has been put in this record by the defendants in this case. Third, he has stated that the tables do not contain any reference to the stage of the river, or the temperature of the air or water. These determinations do appear upon the table. And for the further reason that it does not state whether there was present in this water pathogenic or other micro-organisms, which facts do appear in the tables, and to which reference will hereafter be made. And for the further reason that the final question as to whether these tables prove certain facts or not, goes to the weight of the evidence and not as to its competency.

THE WITNESS: The tables referred to are as follows:

TABLE 1.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

TABLE 23.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

SOURCE OF WATER — MISSISSIPPI RIVER. 100 FEET FROM ILLINOIS SHORE, ALTON, ILL.

Report of ARTHUR W. PALMER,
T. J. BURRILL,
University of Illinois.

Serial No.	Date of: 1899 Collection.	Date of: 1899 Examination.	Appearance: Turb'y.	Appearance: Sediment.	Appearance: Color.	Odor.	Residue on Evaporation: Total.	Residue on Evaporation: Dissolved.	Residue on Evaporation: Suspended.	Loss on Ig'n: Tot'l	Loss on Ig'n: Dis-solv'd	Loss on Ig'n: Sus-pnd'd	Color on Ignition.	Chlorine.	Oxygen Consumed: Total.	Oxygen Consumed: By Dissolved.	Oxygen Consumed: By Suspd Matter.	Nitrogen as Ammonia: Free Ammonia.	Albuminoid Am.: Tot'l	Albuminoid Am.: Dis-solv'd	Albuminoid Am.: Sus-pnd'd	Organic Nitrogen: Total.	Organic Nitrogen: Dissolved.	Organic Nitrogen: Suspended.	Nitrogen as: Nitrites.	Nitrogen as: Nitrates.	Height of Water.	Temperature of Water, C.	Temperature of Air, Cent.	Presence or Abs. of Coli.	No. of Bac. per Cubic Centimeter.

MR. JEFFRIES: Let me ask the witness a question.

8297 JUDGE SPRINGER: Certainly.

Q. MR. JEFFRIES: Professor, did you prepare these tables yourself?

A. I did.

Q. They are not the original tables, are they?

A. Yes.

Q. The original sheets upon which the records was made?

A. Not this piece of paper, no.

Q. That is a printed sheet is it not?

A. It is.

Q. And your original was in pen and ink?

A. Yes sir.

MR. JEFFRIES: That's all.

Q. JUDGE SPRINGER: Did you read the proof sheets after they were set up by the printer?

A. I did.

Q. Did you compare them with the papers that you had prepared in the first instance?

A. I did.

Q. Did you make the necessary corrections, if any were required for the purpose of making this table correspond with the sheets that you prepared in the first instance?

8298 A. I did.

Q. Then do you state that these tables as well as the other sheets to which you referred, were prepared by you and and under your direction?

A. I do.

Q. Who received these samples of water at the laboratory at the University of Illinois?

A. I did, I and my helpers.

Q. When the sample was received, what entries were made upon the certificate accompanying the sample in addition to those already on the sample and placed there by the water takers?

A. The date and hour of reception at the laboratory, and a serial number, was placed upon the certificate which accompanied the sample and the number, the same serial number was placed upon the bottle containing the sample.

Q. State where those serial numbers appear in table No. 1, for instance?

A. In table No. 1, and in all the rest of the eighty tables now referred to, the serial number appears at the left hand of the table.

Q. What is contained in the next column to that?

A. In the second column the date of collection which was
8299 put upon the certificate by the collector, has been put upon the table to indicate throughout, the respective dates of collection of the various samples.

Q. And what is contained in the next column after that?

A. The third column contains the date upon which the sample was delivered at the laboratory.

Q. And these various entries appear upon all the tables from 1 to 80?

A. They do.

Q. I see in the columns following, under the head of "Appearance," the words "turbidity," "sediment," "color" and "odor." State how those determinations were reached?

A. Turbidty was determined by inspection of the sample. Note was made of the relative degree of turbidity of this way, and the results recorded under the various terms "decided," "very decided," "distinct," "very slight" and "slight," as appears in the tables.

Q. And the initial letter of these words was used to indicate those conditions, was it?

A. No, an arbitrary printers' sign, the star or asterisk, and so on, were used for indicating the turbidity.

Q. And what does the star indicate?

A. The star indicated a decided turbidity.

8300 Q. And what does the section mark indicate?

A. The section mark indicated a very decided turbidity. That is, greater turbidity than that which was designated as "decided." The dagger indicated a distinct turbidity, which means less than "decided" turbidity.

Q. The double dagger?

A. The double dagger indicated a very slight turbidity. That is, if turbidity was noticeable, but very small, it was indicated as very slight, and the indication recorded in the printed tables by this sign.

The vertical parallel indicated a slight turbidity. No attempt was made to determine the turbidity with great accuracy for the reason that all of these waters are naturally ordinarily quite turbid, and for the purposes of the chemical investigation, any more close determination of the turbidity seemed to be superfluous.

Q. In what manner did you determine the presence of sediment?

A. When the sample was received note was taken of the quantity of matters lying upon the bottom of the bottle, such substances as sand and clay, and so on, which had settled during the course of time of transport to the laboratory, and an idea as to the amount of sediment was made or developed at this time. Again, that portion of the sample which was not immediately taken, after thoroughly shaking, for the determinations of the
8301 nitrites and nitrates and such constituents as are particularly susceptible to change, was left standing over night, and again the relative quantity of sediment deposited during the standing over night was noted. The results of such observations were recorded roughly by the terms "considerable," "much," "very much," "little," "none." A better idea of the amount and nature of the suspended matter is to be had from the figures recorded in the respective columns of the table under the headings, "total solids," "suspended matters," "loss on ignition," "suspended matters," "oxygen consumed by suspended matters," "albuminoid ammonia in suspended matters," "total organic nitrogen in suspended matters."

Q. What did you determine in reference to the color of the water?

A. The color of the water was determined by the method described previously and was recorded in the tables in terms of the quantity of nitrogen as free ammonia, which developed the same color when it was treated with the Nessler reagent by the method indicated under the determination of free ammonia. Thus the color recorded as "1," represents the color as developed by the Nesslerization of a solution containing one cubic centimeter of the standard ammonic chloride solution, diluted
8302 to fifty cubic centimeters with ammonia free water, or in other words, fifty cubic centimeters of the solution which contains ammonic chlorate equivalent, to .01 of a milligram of

nitrogen. The color recorded in the tables above, the figure "1" indicates .1 of the amount just referred to; that is, indicates a color corresponding to that developed by a solution containing .1 of a cubic centimeter of the standard ammonic chlorate solution, diluted to fifty cubic centimeters with ammonia free water and Nesslerized by the method above indicated.

Q. State what determinations were made in these tables under the heading "residue on evaporation?"

A. The residue on evaporation was determined by the methods before described. They include the total residue on evaporation, the total loss on ignition, the residue left on evaporation of the filtered solution, which give a direct determination of the total matters in solution and the loss upon ignition of the same. The determination of the suspended solids being indirect, that is, the figures recorded in the tables being the difference between the figures representing those matters in solution and the figures representing the total solid matters, which latter include of course both the dissolved substances and those which are suspended merely in the water.

8303 Q. I see you have a column here headed "color on ignition." That is indicated by the various letters used in these tables, is it not?

A. The color on ignition, yes.

Q. And the word "the" is explained in the note below, and also the other letters?

A. Yes, sir.

Q. State whether the explanation by certain letters and signs, are correctly explained with corresponding letters and signs in the note at the bottom of each of the tables?

A. They are. Now, with reference to the color there, I should put in the designation. In the column where the record of the color is made, there appears two letters, "M" and "F." The M here refers to the fact that the water was muddy, and that consequently it was necessary to filter it in order that the color be determined. The letter F refers to the fact that the sample so designated was filtered before the color examination was made.

Q. What does the figure .5, for instance, at the top of the first column refer to?

A. This indicates that the color of the filtered sample of

water referred to, was equal to the color developed in 50 cubic centimeters of a mixture of water and ammonic chloride
8304 solution, of which the ammonic chloride solution constituted or consisted of half a cubic centimeter of the standard ammonic chlorate solution used in Nesslerization. The whole entry for this particular sample with respect to the color reads: "The sample was muddy, consequently it was filtered, and the filtered sample had a color corresponding to the half of a cubic centimeter of ammonic chloride as determined by the method just described.

Q. Take the next to the last line in that table which says "M. F. .30." What is the meaning of the figure .30?

A. Here the M means muddy, the F, filtered, and the .30, is in reality .3. Through some oversight, the printer got in an additional figure, the insignificant cipher,—insignificant because here it means nothing.

Q. State whether in all the tables from 1 to 80, inclusive, these letters and figures mean the same?

A. They mean the same throughout the entire set of these tables?

Q. Now, returning to the other columns under the head of "chlorine" you have entered what figures?

A. 102. This shows that the result of our determination, my determination of chlorine in the sample No. 4974 showed the sample to contain 102 parts of chlorine per million parts of sample.

8305 Q. Do the entries succeeding that to the end of these tables indicate the same thing?

A. They throughout indicate similar things. That is, the same sort of things with respect to each sample.

Q. That means the chlorine in different quantities?

A. Yes, sir.

Q. Now, in reference to oxygen consumed, you have three columns, what do they indicate? On the first line we will say of the first table; table 1?

A. In the first column, total oxygen consumed. That is the oxygen consumed in the determination upon the original sample without filtration. It showed in this particular sample, No. 4974, that the quantity of oxygen required or consumed, was 39 parts per million parts of water. Similar figures throughout this and corresponding columns in the other tables show similar facts with respect to the oxygen consumed, by the various different samples of water.

In the next column, under "Oxygen Consumed," that by dissolved substances, the determination was made, in a portion of the sample which had been filtered, thus removing the suspended matters. The determination was made by the same method; the results were entered in the second column, and the figure in the second column shows the amount of oxygen required by a million parts of water. That is, the 21. 8306 shows that 21 parts per milion of ogygen were required for the oxidation of organic matters in solution under the conditions prevailing in the entire series of determinations of oxygen consumed.

The third column contains the figures which represent the oxygen required or consumed by suspended matter, and shows these quantities as determined by the difference between the oxygen consumed by dissolved matters directly determined as indicated above, and the oxygen consumed by all matters contained. That is, by those in solution and those in suspension and recorded in the column under "total." The figure 18 under this column, under oxygen consumed by suspended matters, shows that the suspended matters in a million parts of water require 18 parts of oxygen for their consumption. It is the difference between the figures in the two next preceding columns.

Q. Under the columns headed nitrogen as ammonia you have determinations of free ammonia and albuminoid ammonia. Will you please state what is indicated by the figures in the column headed "free ammonia?"

A. In the column marked "free ammonia" under the general head "Nitrogen as Ammonia," the figures 13.6 shows the results of our determination of free ammonia in sample 4974 by the methods previously described. The figures 13.6 repre- 8307 sents the fact that 13.6 parts by weight of nitrogen as free ammonia, were contained in a million parts of sample No. 4974.

In the next column under the general title "Nitrogen as Ammonia," secondly titled "Albuminoid Ammonia," tertiary title "Total," figure 2.4 represents the quantity of albuminoid ammonia contained in or formed from the matters in solution and in suspension in the sample No. 4974. In the next column under the term "Dissolved" 1.44 the figure represents the quantity of nitrogen as albuminoid ammonia contained in solution. It was determined similarly to the total albuminoid ammonia, but upon a portion of the sample of water which had been filtered before the determination was made, the 1.44 indicates the fact that the sample in question contained in one million parts, 1.44 parts of nitrogen as albuminoid ammonia in solution, or, rather, nitrogenous organic matters corresponding to nitrogen as albuminoid ammonia in solution.

The third column under secondary title "Albuminoid Ammonia," represents the nitrogen as albuminoid ammonia derived from the matter suspended in the sample of water No. 4974, and it is determined indirectly, that is, by the difference between the two direct determinations, namely that of the total nitrogen as albuminoid ammonia and that of the nitrogen as albuminoid ammonia in solution, recorded in the column marked "Dissolved" in the table.

8308 Q. Under the general heading of "Organic Nitrogen" you have prepared three columns of figures, will you please explain what they indicate in reference to the sample about which you have been speaking, the first sample in table 1?

A. The heading "Organic Nitrogen," as it appears in table 1 and the other 79 tables of this set, refers to the total organic nitrogen as determined by the Kjel Dahl method hereinbefore described, and the three columns which appear under this general heading, contain the figures which show the quantities of the total organic nitrogen in the unfiltered sample, which includes the organic nitrogen of substances in solution and also the organic nitrogen of substances in suspension. In the column designated "Dissolved" the figure appearing represents the results of the same determination made upon a portion of the sample of water which had previously been filtered. In the third column under the heading "Suspended" the figures which appear represent the quantity of total organic nitrogen contained in the matters or substances which are held in the water merely in suspension, and not in solution or dissolved. This determination is made indirectly; that is, the figures appearing in this column represent the differences between the figures appearing in the first and second columns, under the general title

8309 "Organic Nitrogen" which two figures have been determined directly and only the last, that is, the suspended matters, determined indirectly or by difference.

Q. Under the general heading "Nitrogen as Nitrites or Nitrates," please explain what these figures indicate in reference to the first sample recorded in table 1?

A. In the column marked "Nitrites" under the general term "Nitrogen as Nitrites" the figure appearing represents the quantity of nitrogen as nitrites appearing in the sample contained in number 4974 and represented in parts per million. That is, the figure .005 represents the fact that in 1,000,000 parts of this sample there were contained .005 of one part of nitrogen as nitrites.

Q. In the next column what have you indicated?

A. In the next column which represents the nitrogen as nitrates, the figure .15 represents the fact that in the sample 4974 there were found .15 of one part of nitrogen as nitrates in one million parts of the original sample.

Q. You have now indicated the significance of the entries made in table No. 1, in reference to sample 4974. Please state whether a similar explanation is applicable to all samples recorded in the tables numbered from 1 to 80, inclusive?

A. This same explanation applies to all of the entries in 8310 this table and the other 79 tables of this set, with the simple exception of the differences in the figures and the letters pertaining to the results obtained for the individual samples as set forth in the tables.

Q. I see upon this table No. 1, certain entries in columns indicating the height of water, temperature of water, temperature of air, presence or absence of the bacillus coli communis, and the number of bacteria per cubic centimeter; will you please state who made those entries upon this table?

A. These entries pertaining to the bacterial examinations were made by Prof. T. J. Burrill, bacteriologist of the University of Illinois, who had charge of the bacterial examinations made at the University of Illinois.

JUDGE SPRINGER: I will state to counsel that we will call him subsequently for the purpose of testifying to these two columns.

A. The entries under "Temperature of Water," "Temperature of Air," "Height of Water," were made partly by me and partly by Professor Burrill, and were transcribed from the original certificates sent in by the various collectors and may all be found by reference to the original certificates which are on file in the possession of the court.

8311 MR. JEFFRIES: Complainant moves to strike out all the testimony of this witness in explanation of the tables just read in evidence for the reasons stated in the objection to the introduction or the reading of the tables into the record, and to strike out all that part of the tables and the explanation of this witness which refers to sediment in the samples of water so examined by this witness, for the reason that it has not been proven by the defense that the question of sediment is not to be considered of moment in passing upon the sanitary condition of the water, unless at the same time the source of sediment be considered. That certain water might contain large quantities of sediment, and yet contain no disease producing organisms, chemically speaking, or speaking from a sanitary standpoint. Upon the other hand it might contain no sediment, and at the same time be teeming with living disease producing organisms. I move to strike out all reference to the color of the samples taken for the same reason and all reference to the column referring to the odor of the water for the reason that water without odor has been known to be teeming with living disease-producing organisms.

I move to strike out the column with reference to residue on evaporation for the reason that the determinations therein made throw no adequate light upon the determination of the sanitary condition of the water. I make the same motion

8312 as to the oxygen consumed, nitrogen as ammonia, organic nitrogen and nitrogen as nitrites and nitrates, for the reason that there is evidence showing that none of these qualities contained in water, are of a disease producing character, and for the further reason that their determination does not correctly portray the sanitary condition of the water with reference to its containing disease producing organisms or living organisms of a disease producing character.

I move to strike out all reference to the tables by this witness for the reason that an insufficient number of samples have been examined for the determination of the sanitary condition of the water at all times and at all seasons of the year, from chemical analysis pure and simple, and that samples so taken and examined have not covered a sufficient length of time to determine exactly the chemical condition as well as the sanitary condition of the water at all times of the year, and for the further reason that in the analyses and by failure to cover the entire year, the question of flood times and low water seasons was not considered, and is not sufficiently considered, and is not shown by the tables, and for the further reason that the evidence on the part of the defense shows that certain chemical changes will be produced and brought about in the time of the transfer from the places 8313 of collecting the samples to the laboratory and before the sample is analyzed chemically, so that the chemical constituents of the water analyzed, at the time the analyses were made do not correctly portray the exact chemical condition of the water at the time the sample was taken, aside from the sanitary condition of the water, at the time and place.

JUDGE SPRINGER: I move to strike out this objection for the reason that it goes merely to the weight of the evidence and not to its admissibility, and for the further reasons stated by me in my motion to strike out the objection of counsel to the reading of these tables in evidence.

MR. TODD: I desire to add by way of answer to the objection, not conceding the conclusions stated in counsel's objection, that the complainant in its original case has introduced several thousand pages of testimony of a chemical and bacteriological character and has also introduced the testimony of Whipple in regard to questions of coloration for the purpose of establishing the unsanitary condition of the water for domestic and drinking purposes, and in view of this enormous amount of tstimony offered by complainant on the same line which they now object to defendants introducing evidence, and without conceding the conclusions mentioned in the objection, this testimony is admissible if for no other purpose than for the 8314 purpose of rebuttal, which is not the sole and only purpose for which it is offered, but is offered as affirmative evidence for the establishment of the contentions set up in the answer of the defendants.

Q. JUDGE SPRINGER: Professor, the tables which you have read in evidence, beginning with table No. 1 and ending with table No. 38, contain, as you have stated, your analyses of water, the samples of which were taken during the year 1899. Will you please state whether you made any general averages of the results of the samples taken for that year?

A. I have made averages of all results of my analyses of the samples collected from each of the points under consideration during the year 1899.

Q. I will ask you to look at the table which has been designated as table "A"—Streams Examinations, Sanitary District of Chicago, Sanitary water analysis, parts per million, averages of results, for the year 1899, and the report of Arthur W. Palmer, of the University of Illinois, and ask you to state whether that table contains the averages made by you of your chemical analyses of the waters under investigation and indicated in the tables which I have mentioned, beginning with 1 and ending with 38?

A. I identify this table as tableA,—which is designated
8315 as table A, as being the one which I prepared, and as
representing the general averages for the year 1899 of the figures appearing in tables 1 to 38, inclusive.

Q. I call your attention to the first line in this table A, and you will please designate or indicate the averages indicated by that line?

A. The first line in table A gives in the first column, the number of the station, that is, the point at which the samples were collected, and indicates also table 1, in the set of 80 which has been hereinbefore described. The point is Bridgeport, Illinois and Michigan canal. This designation appearing in the second column under the caption "Source of Water." In the third column "period covering" for 1899, there appear dates April 27th, December 26. These dates represent the dates of the first and last collections made during 1899 from that particular source.

In the next column, "Average of," there is given the number of samples upon which the average was made. That is, the figures in this column represent the numbers of different samples taken during the period indicated in the year 1899, the results of which are entered in tables 1 to 38, inclusive, referred to above, and upon which the averages were made.

Under residue on evaporation, total, the figures
8316 584.1 represent the general average of the residue on

evaporation determined in the 22 different samples collected at this point.

In the next column figure 499.7 under the term "Dissolved" represents the average content of solid matters in solution in the samples of water collected during 1899, covering the period April 27th to December 26th, from the Illinois and Michigan Canal at Bridgeport.

The figures 85.4 appearing in the third column under "Residue on Evaporation," refers to the suspended matters and shows the average quantity of matters contained in suspension in the 22 samples of water referred to. Under the "loss on ignition" the figures 65.1 in the column designated "Total" and the figures 39.5 in the column designated "Dissolved," and the figures 25.9 in the column designated "Suspended" represent the averages of these different determinations made in the 22 samples of water derived from this source, the details of which appear in table 1 above referred to.

Q. What's that?

A. The details of the analyses of the 22 samples and the other figures in these columns, refer in a similar manner to the averages of the various samples, the analyses of which appear in detail in the tables 1 to 38 inclusive.

8317 Now, in the next column, under the heading "Chlorine" there appear figures representing the averages determined in the same manner for the chlorine, as the entry in this column 124.2 represents the fact that the average content of chlorine in the 22 samples of water collected from the Illinois and Michigan Canal at Bridgeport during the period from the 27th of April to the 26th of December, 1899, inclusive, was 124.2 parts of chlorine in a milion parts of water, and the other figures appearing in this column in table A represent the various averages of the chlorine determinations which appear in detail in the tables 1 to 38, inclusive.

The figures appearing in the column under "Total Oxygen Consumed" show similar averages for this determination. The number 35.1 the first entry in this column represents the average quantity of oxygen consumed by the 22 samples of water collected at the point above repeatedly mentioned during the period April 27th to December 26th, 1899, and the other figures in this column represent similar averages of the total oxygen consumed by the various samples, details of the determinations of oxygen consumed, appearing in the tables 1 to 38, inclusive.

The figures in the column under "Oxygen Consumed by Dissolved Substances and by Suspended Matters" represent similar averages to those heretofore explained.

8318 Under "Nitrogen as Ammonia" the entries in the column under free ammonia refer to similar averages of the free ammonia contained in the various entries as shown in detail in the tables 1 to 38, inclusive.

Under "Nitrogen as Ammonia," secondary title "Albuminoid Ammonia" in the column marked "Total" and in the column marked "Dissolved" and in the column marked "Suspended" the various figures represent similar averages for those various different determinations as given upon the detailed records of tables 1 to 38, inclusive.

Under "Organic Nitrogen" the figures appearing in column marked "Total" and those in column marked "Dissolved" and those in column marked "Suspended," represent similar averages for those different constituents as set forth in detail in the tables 1 to 38, inclusive, but here brought together in the form of general averages, as in the other cases disclosed with respect to this table "A."

Under the columns marked "Nitrogen as Nitrites and Nitrates" the various figures entered represent similar averages for these different constituents which averages were determined from the detailed notations in tables 1 to 38, as indicated above.

8319 Q. State whether the lines of this table A, following the ones to which you have just been testifying and including in that No. 38, Mississippi river at Jefferson Barracks, west shore, contain similar averages for the points mentioned under the head of sources of water, and for the times indicated in the column headed "Period covering 1899?"

A. They do.

Q. Will you please read this table A in evidence?

A. The table—

MR. JEFFRIES: I object to the witness reading the table of averages in evidence for the same reasons stated in my objection to the reading of the table in evidence.

A. The table is as follows:

TABLE A.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

AVERAGES OF RESULTS FOR YEAR 1899.

Report of ARTHUR W. PALMER,
University of Illinois.

No. of Station.	Source of Water.	Period Covering 1899	Average of	Residue on Evaporation.						Chlorine.	Oxygen Consumed.			Nitrogen as Ammonia.				Organic Nitrogen.			Nitrogen as

8321 Q. JUDGE SPRINGER: Professor, I now call your attention to tables Nos. 39 down to and including table No. 80, which you have read in evidence and ask you whether you made similar averages for the samples taken in the year 1900, which are embraced in these tables, as in the table you have just testified in regard to for the year 1899?

A. I did.

Q. I hand you a paper marked Table B, Streams Examination, Sanitary District of Chicago; Sanitary Water Analyses, Parts per million; averages of results for year 1900, report of Arthur W. Palmer, University of Illinois. Please state whether that table contains the averages that you made of chemical analyses taken from samples of water in the year 1900, and to which you have previously testified, and the results of which samples are recorded in tables beginning with No. 39 and ending with table No. 80, inclusive, already read in evidence by you?

A. It does.

Q. Please read the table in evidence.

MR. JEFFRIES: To the reading of which table in evidence complainant objects for the same reasons stated in the objection to the introduction of the tables from which the averages are made.

A. The table is as follows:

TABLE B.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

AVERAGES OF RESULTS FOR YEAR 1900.

Report of ARTHUR W. PALMER,
University of Illinois.

RECORD

The State of Missouri

vs.

The State of illinois

and

Sanitary District of Chicago

VOL. 6

IN THE

Supreme Court of the United States

THE STATE OF MISSOURI
vs.
THE STATE OF ILLINOIS
and
THE SANITARY DISTRICT OF CHICAGO.

Original,
Docket No.

Before
FRANK S. BRIGHT,
Commissioner of the Supreme Court of the United States.

VOLUME 6.

A—316a

VOLUME 6.

2:00 p. m., Tuesday, October 13th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ARTHUR W. PALMER,

resumed the stand for further direct-examination by Judge Springer and testified as follows:

Q. Professor, referring again to tables numbered 1 to 80, inclusive, which you have read in evidence, please state whether you made any averages based upon those tables for the years 1899 and 1900, based upon the chemical analyses of water taken from the places indicated in those tables for the months of June, July, August and September, respectively, of those two years?

A. I did, and these averages are given in tables C and D, respectively.

Q. Please look at the tables which I now hand to you and state what they are, in the first place, and what they contain in a general way?

A. Table C contains the averages of results for the period June, July, August and September, 1899; averages made from the detailed analyses appearing in tables 1 to 32, inclusive,
8324 but for only such samples of those tables as were collected during the period mentioned, namely, June, July, August and September.

Q. State whether the respective columns of figures contained in those tables were prepared in the same manner and represent similar results as those contained in the averages which you have read in evidence contained in tables A and B?

A. The columns and the figures which appear in the various columns of table C represent just such averages as I have described in my statement regarding tables A and B, and they were prepared in similar manner, but for the period of four months, June, July, August and September, only, instead of for the entire period of the year 1899.

Q. You will please read those averages then into the record as part of the evidence in this case?

MR. JEFFRIES: To the reading of which table complainant objects for the reasons stated in the previous objection to the reading of tables A and B.

THE WITNESS: This table is as follows:

TABLE C.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

AVERAGES OF RESULTS—For Period June, July, August and September, 1899.

Report of ARTHUR W. PALMER,
University of Illinois.

III

8326 THE WITNESS: Table D, made in a similar way and bearing similar relation to tables A and B, and to the tables 39 to 80, inclusive, identified as containing general averages for the period, June, July, August and September, 1900.

Q. Will you please read that table now in evidence?

MR. JEFFRIES: To the reading of which complainant objects for the reasons stated in our objection to the reading of tables from which the general averages contained in this table, were obtained.

THE WITNESS: The table is as follows:

TABLE D.

8328 Q. Did you make any averages based upon the chemical analyses of waters taken from the streams indicated in tables 1 to 80, inclusive, showing the averages for June, July, August and September, for the two years, 1899 and 1900, in one table, placing the respective determinations in succeeding lines and columns?

A. Table G which you have just handed me is recognized by me as one in which I brought together some of the averages of tables C and D, for the purpose of comparison of the results, covering the two four months periods, namely, June, July, August and September, 1899, and June, July, August and September, 1900, and I also gave in that table the highest and lowest figures of various determinations made during the periods in question. I note one typographical error in that table, namely, Mississippi river at West Alton, should read Missouri river at West Alton, and I now correct this mistake.

Q. State whether the determinations set forth in that table as the result of the chemical analyses to which you have referred are now, after making the correction, the averages of the results which the table purports to make?

A. It is a comparison of some of the averages from the preceding tables of averages, and includes also some in-
8329 dividual data from the tables 1 to 80, inclusive, from which I have selected the highest and lowest figures of the determinations, occurring within this period,—four months in the summers of the two years respectively.

Q. Will you now read that table G into the record?

MR. JEFFRIES: To the reading of which said table complainant objects for the reason that all of the averages are not employed in making the comparison, and for that reason it is incompetent, irrelevant and immaterial and does not purpose to give any information with reference to the continually existing comparative relations between the various streams of waters,—the waters of which were analyzed by this witness.

THE WITNESS: The table is as follows:

TABLE G

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

For Period June, July, August and September, 1899-1900.

Report of ARTHUR W. PALMER,
University of Illinois.

8331 Q. I now hand you a paper, Professor, which is designated as table H. Please state what ascertainments you have made and entered upon that table?

A. Table H comprizes a comparison of the general averages of all the work during the years 1899 and 1900, which appear in tables 1 to 80, inclusive, so far as the entries under the different columns in table H are made, and these averages, together with the individual highest and lowest determinations of a number of constituents, are brought together for the purpose of comparison of the condition of the water as between the two years, so far as these two years are covered by the series of examinations which appear in tables 1 to 80, inclusive.

Q. Will you please read that table in evidence?

A. I will.

MR. JEFFRIES: To the reading of which we object for the reasons stated in our objection to the reading of the previous tables into the record, and also for the reasons stated in our objection to the reading of the tables from which this table of general averages is taken.

THE WITNESS: The table is as follows:

Table H.

STREAMS EXAMINATION—SANITARY DISTRICT OF CHICAGO.

SANITARY WATER ANALYSIS—PARTS PER MILLION.

For Years 1899-1900.

8333 Q. Did you make any ascertainment of the dissolved oxygen in the water of the respective streams mentioned in tables numbered 1 to 80, inclusive, that you have already read in evidence?

A. I did.

Q. State whether you entered those determinations upon any tables, and if so, whether the tables that I now hand to you which contain a designation at the bottom of each page, as 95a, 95b, 95c, 95d, 95e, 95f and 95g, contain the results of those ascertainments?

A. I do identify these tables, 95a, 95b, 95c, 95d, 95e, 95f and 95g, as containing the results of various determinations of dissolved oxygen in samples of water from the various points in the Ilinois river, and some of its tributaries and the Mississippi river.

Q. What period is covered by these determinations?

A. These determinations range over the period from the beginning of the work early in 1899, to the discontinuance of the work in the year 1900. That is, from the latter part of April, 1899, until about the middle of October, 1900.

MR. JEFFRIES: Let me ask the witness a quetsion.

Q. Professor, were these determinations made from the same samples that the other determinations were made from?

8334 A. No.

Q. It was a separate set of samples, then, altogether?

A. Yes, but in most cases collected at the same time. Those which we took on the spot of course, were separate from the others. In some cases they were collected simultaneously with the large samples that were used for chemical analysis, but in all other cases all shipped samples were collected at the same time as the bacterial and chemical samples.

MR. JEFFRIES: I object to this testimony and move to strike out the answers of the witness for the reason that it is not shown that the samples of water were properly taken, or the manner in which they were taken, or the point in the river from which they were taken, and for the further reason that this testimony, on account of the variations in the taking of the samples and the analyses of the water, being different from that with reference to the manner in which, and the time at which the samples were taken with reference to the tables heretofore introduced in evidence, is not comparable and do not accurately portray the condition of the water at the places taken with reference to dissolved oxygen at all times, and further for the reason that there is no evidence showing the extent that dissolved oxygen was affected by means of the 8335 collection of samples, their transportation and their manner of being handled in the laboratory or en route.

JUDGE SPRINGER:

Q. I will ask you, Professor, to look at the tables which I have placed in your hands, numbered at the bottom 92a to 95g, inclusive, and state the manner in which the collections were made, and all the facts which are intended to be conveyed by these tables?

MR. JEFFRIES: That is objected to for the same reasons stated in the previous objection.

JUDGE SPRINGER: Perhaps this statement will remove some of your objections.

A. Most of the samples, determinations upon which are recorded in these tables, 95a to 95g, inclusive, I collected myself, and analyzed myself, following the methods which I have previously described in giving this testimony so far as the determination was concerned. With respect to the manner of collection I may say that the collection in some cases was made by immersing the special pipette referred to in my description of the method, in the water of the stream to be examined, to a depth of eighteen inches, and after the pipette was in this manner filled by closing the cocks to confine within the pipette the full 8336 volume which the pipette might hold, namely, 107 cubic centimeters, and thus withdrawn from the stream within the pipette, shut off entirely from the atmosphere, the sample in which the dissolved oxygen was to be determined. In other cases the collection was made by means of a rubber syringe bulb, so arranged as to draw the water from the stream and force it into and through the bottle in which the sample was to be taken, or into and through the pipette in which the sample was to be analyzed, and where the dissolved oxygen was determined at greater depth than eighteen inches below the surface, there was attached to this syringe a tube which reached to nearly the bottom of the stream, varying in length as the depth of the stream

varied at different places. The samples which were not collected by myself, and they include only a portion of the samples collected at Grafton, that is, part of those collected from the Illinois river at Grafton, and part of those collected from the Mississippi river at Grafton, were collected for me by a collector, who had been specially instructed how to collect, who had helped me collect when I was on the spot doing the work for myself, and who further was the regular collector of the samples at Grafton, both from the Mississippi and the Illinois river, for the regular bacterial and chemical examinations. The collections at all
8337 other points referred to in these tables I made myself.

Q. Will you please explain the object of this determination and the significance of the column where you have indicated the results?

A. Where the results are indicated?

Q. Yes, "M. G.," "temperature," etc.

A. In the series of three columns for which the heading is milligrams per liter, represented by the ordinary abbreviation, capitals "M. G." for milligrams, there appear the results of determinations upon duplicate samples in the first two columns, and the average of these two determinations in the third column, save where in a few cases from lack of time, duplicate determinations were not made.

In the next column is given the temperature of the water, which determination was made by the one who took the sample,—in mose cases myself. In the cases hereinbefore mentioned, by the specially instructed collector.

In the next column after the one in which the temperatures are recorded, there appears under the general heading "Per cent. of saturation," figures which represent that portion of the possible quantity of dissolved oxygen which was actually contained in the water. That is, it is well understood that
8338 under the conditions of exposure to the atmosphere, these will be modified somewhat by atmospheric pressure, modified very largely by the temperature of the water. The proportion of oxygen which the water may hold in solution varies, and the maximum which can be held in equilibrium in solution at any given temperature is called the saturation figure, and when the water is fully saturated it is regarded as holding

100 per cent. of dissolved oxygen, which means all that the water can normally, under the given conditions, retain in solution.

Q. Please state whether the succeeding determinations as to the sanitary canal, Kedzie avenue, Desplaines river, Joliet, etc., down through all the tables, including 95g, were made in the same way as that which you have just explained?

A. They were all made in practically the same manner, except that a few of the analyses or determinations of dissolved oxygen included in these tables were made by the well known Winkler's method.

Q. Have you explained what that method is?

A. Well, I have not done so. I can if it is necessary. The Winkler method for the determination of dissolved oxygen depends upon the fact that dissolved oxygen or free oxygen acts upon manganous hydroxide, oxidizing it to manganic or the higher oxides or hydroxides of manganese, and the higher
oxide of manganese thus produced, re-acting with a solu-
8339 tion containing hydiodic acid, sets iodine free, which sub-
sequently is measured by titration with a standard solution of thiosulphate of sodium. The collection of the sample for dissolved oxygen by the Winkler method is made in essentially the same manner as has been described in the Levy method, with the exception that no special pipette is used in this method, but that a bottle of convenient size, which may hold about a quarter of a liter of water, but of which the capacity must be known precisely, is filled with the water. Then there is introduced a concentrated solution of manganese sulphate or maganese chloride. Next a strong solution of sodium hydroxide, and without permitting air to come into contact with the mixture within the bottle other than merely momentarily with it at the surface exposed in the neck of the bottle. The stopper is inserted excluding all air, and the contents of the bottle mixed. The alkali precipitates manganous hydroxide, which is almost white or pinkish white. Any dissolved oxygen in the water immediately affects this manganous hydroxide, changing some of it into manganic compounds which have in the pure state a dark brown color. The manganous compounds do not affect the solution of hydriodic acid. The manganic do, and set free from such solution iodine in the elemental condition. The dissolved oxygen oxidizes the manganese; the manganese oxidizes the

hydriodic acid, giving free iodine. The free iodine
8340 strikes a blue color with starch paste, which in small quantity is used as an indicator, and then by titrating this mixture with thiosulphate of sodium, a standard solution, from the quantity of this latter solution required, the quantity of iodine, and from it the quantity of dissolved oxygen is readily calculated after the shaking of the mixture in the bottle, after the oxygen has been absorbed by the manganese compounds, the mixture after completion of this reaction, is acidified and potassium iodide added, the acidification sometimes taking place before, sometimes after the addition of the iodide of potassium, but in all cases before the mixture in the bottle is exposed to the air. With waters containing considerable organic matters, nitrites and so on, it is necessary to run a blank determination with the water in order to make corrections for the effect of such impurities upon the different solutions used in making the determination. These corrections were made by treating a measured quantity of the water sample with manganic chloride and noting the amount of reduction that was effected in this solution during the lapse of from two to five minutess, according as it seemed best to vary the times, for reasons determined by the time taken in making the direct determination upon the particular sample, although ordinarily five minutes was the length of time allowed for the action of the
8341 impurities in the sample upon the maganic chloride used
in determining the blank.

Q. In the column headed "Remarks" I find the statement "Test of keeping qualities" opposite certain lines. Will you explain what that means?

A. Why, in some cases, even where the work was done on the spot, and for the reason of getting some information as to what changes take place during transportation from the point of collection to the laboratory, samples collected simultaneously with those in which the determination was made as the water came from the stream, were set aside and kept sometimes ten or twelve hours, sometimes until the next day, sometimes two days. The test of keeping qualities applies to this, for the reason that it is found that waters containing notable quantities of organic matters frequently suffer a loss of dissolved oxygen when the samples are allowed to stand out of their natural environment, that is, taken out from the stream in which they normally are found, or from which they have been collected. If there is a great diminution of the quantity of dissolved oxygen, then the keeping qualities are regarded as being inferior to what they are in case there is less diminution on standing.

8342 Q. How were these samples of water shipped to you, and where did you receive them?

A. These samples of water were collected in self-sealing or quick-sealing magnesium citrate bottles, bottles of heavy glass, provided with a combined metal and rubber stopper, which is so fastened to the neck of the bottle by means of heavy wires, that the bottle can be quickly and securely closed by insertion of the stopper, which the wires keep in place, and subsequently when it is necessary to open the bottle by removing the wires, the stopper is removed and the contents may be easily accessible. The bottles employed held from 350 to 400 cubic centimeters of water and special effort was always made in filling the bottles to exclude totally every bubble of air, that is, to have the bottles entirely filled with water and nothing but water, with its various ingredients. These bottles were packed in small special cases each case holding one dozen bottles, each bottle in its own separate compartment, and the case sealed to exclude light, the case and bottles being shipped together with the case containing the chemical and bacterial samples, and they usually arrived at the laboratory in good condition, with the exception that oc-
8343 casionally bottles were broken in transit from the pressure exerted by reason of increase in temperature of the water during its transit, and oftentimes the expansion caused by decrease in temperature during transit,—from the point of collection to the laboratory.

With reference to my statements concerning saturation of the water with dissolved oxygen, a reference to the column in which the data under this head is given, shows at once that the figures there are in many cases considerably above 100. For instance, under the Illinois river water at Henry above the dam for 1899, under date of August 17th, the first in that series, the percentage shown in the last column under saturation is 220.88. This shows that the water is highly supersaturated, the supersaturation takes place by reason of the fact that the chloriphyl containing organisms with which the river water at such seasons especially abounds, under the influence of sunlight, give off streams of oxygen, which may be seen coming up through the water, and under these conditions the water naturally dissolves much more oxygen than it could under these conditions, dissolve from the atmosphere, and this oxygen for a time remains in the water, although on long standing it undoubtedly would be given off in part into the atmosphere, down to the saturation figure of 100 per cent, and also might in part be utilized by the organic matters in the water, and so the proportion be reduced. 8344

I guess that covers the supersaturation.

Q. JUDGE SPRINGER: Now professor, read the tables to which you have referred Nos. 95a, to 95g.

MR. JEFFRIES: I object to the reading of the tables into the record for the reason that there is no evidence to show that any samples of water were taken in the manner described by the witness or shipped in the manner described by the witness, no water-taker having testified to the taking of any such samples in any such manner, and that while it may be true that the witness took a part of the samples contained in the tables which he is now requested to read into the record, yet the witness has stated that he did not take all of them, that a part were taken by others and shipped to him, and there is nothing in the record to show the manner in which those were taken by other persons, or the manner of shipment and no evidence to show where they were taken, whether from the Illinois river or from some other river.

I object to the reading of the tables for the further reason, because of the failure to show the exact manner in which all of them were taken and the exact places at which all of them were taken; that the examination for the purpose of determining the dissolved oxygen, renders the tables incomparable and unreliable, and as carrying with them no probative force, and for the further reason that they do not disclose the condition of the water of the Illinois river with reference to dissolved oxygen at all times of the year, with reference to the variations in the flow of the stream, the volume of water in the stream, with reference to the various temperatures of the waters in the stream at different seasons of the year. 8345

A. The tables are as follows:

8352 JUDGE SPRINGER: Professor, please state in what capacity you were acting when the samples which were analyzed in these tables just put in evidence, were taken?

A. As collector, as analyst, as investigator of the conditions of the water in the Illinois river and tributaries, and the Mississippi.

Q. At whose instance?

A. Well, I began this work at my own instance, but such portion of it as is included in the tables here under discussion, such portions of the general investigation as are included in the tables 1 to 80 inclusive and the tables of averages, were begun as a result of the conference held March 15th, 1899 at the City Hall, which conference has been described in part by myself and more fully by Dr. Gehrmann, in his testimony. I undertook the work on dissolved oxygen myself, for the purpose of getting information concerning that particular constituent or condition of these waters, as a part of the general investigation in progress, of these various waters.

Q. Did you state who collected the samples that were not contained in the tables 1 to 80 inclusive?

A. You mean those in 95a to 95g?

Q. Yes.

A. Yes, I stated that. I collected most of them. I did
8353 not state before, but I am glad to do so, that some were
collected by Mr. B. F. Robinson of Grafton, Illinois.

Q. State whether Mr. Robinson at Grafton was furnished certificates for the purpose of labeling the bottles, and furnished bottles that had been prepared in the usual way you have described in regard to other analyses, and whether those bottles with the certificates and blanks upon them filled out, came to you from him from time to time, as indicated in these tables, 95a to 95g inclusive.

A. Yes sir. The general certificates for the chemical samples pertain to the bacterial samples also, and further, to the dissolved oxygen samples, but the tags and labels with less detail information were also placed on the individual bottles in which the oxygen samples were collected, that is, the samples of water for determination of dissolved oxygen, but the general features, as the height of the river, temperature of the air, direction of the wind and the recent rain, and the passing of boats and so on, were for all three sets of samples, and put on one certificate.

Q. State whether the bottles that you received from Robinson at Grafton during this period were the same that you had sent to him for the purpose of being filled?

A. They were the same.

8354 Q. Have you any reason to believe that any different method was pursued by him from that which has been indicated on these various certificates?

A. None whatever.

Q. Were you willing to receive those samples from Mr. Robinson, and did you record them as having been taken in the manner that you had instructed him to take the other samples?

MR. JEFFRIES: I object to the question as immaterial, irrelevant and incompetent. It is not a question whether he is willing to receive them or did receive them. His receiving them is no evidence of their being taken in the manner stated, he not being present at the time they were taken and having no personal knowledge of the time and place of taking.

A. I was so willing to receive them and did receive them in the full belief that they were collected, sealed and shipped in accordance with the directions given by me to Mr. Robinson in person.

Q. Please explain the significance which you attach to the ascertainment of dissolved oxygen in the respective waters mentioned in these tables.

MR. JEFFRIES: I object to any question as to their significance for the reason stated in my objection to the reading of the tables into the record.

8355 A. The results of our determinations of dissolved oxygen in some 400 samples of water from the Illinois river have shown that the waters of the Illinois river at all times contained a considerable percentage of the quantity of oxygen which was required for saturation, and that at times it contains much more than the saturation figure; indeed, occassionally at certain points it contains even more than double the saturation quantity. The supersaturation of the water with oxygen, if we may so term it, is due to the liberation of oxygen by the chlrophyl-containing micro-organisms, and other minute plants which are very abundant in the waters of the Illinois at certain seasons of the year. In fact, oxygen-evolving organisms seem to be always present and almost always active in these waters.

Many of the determinations have been made upon the spot, but inasmuch as circumstances rendered it impracticable for us to make very extensive series of determinations in this way, the samples of water were, throughout a considerable portion of the time, shipped to the laboratory and the determinations of dissolved oxygen made there ordinarily in about 24 hours after the time of collection, but sometimes not until 40 or 48 hours had elapsed from the time of collection. These shipped samples
gave results which are always less than the saturation
8356 figure, except on a few occasions, when the original water
was highly supersaturated with oxygen. The exceptions noted from the general diminution of dissolved oxygen during transit, were occassioned by the treatment of some of the samples with mercuric chloride, in which cases there appeared no diminution in the proportion of dissolved oxygen, as the mercuric chloride prevented such changes in the water, as under other circumstances brought about such a decrease of the oxygen contained in solution.

Comparison of the results of determinations made upon the spot with those made upon duplicate samples which were either shipped to the laboratory or kept under similar conditions to those involved in shipping, show that there was in all cases a notable diminution of dissolved oxygen during the time which elapsed between the time of collection, and the time of making the examinations. Consequently, it is certain that the actual content of dissolved oxygen in all these waters was in reality greater than the results here recorded. There was but one case in which a greater percentage of dissolved oxygen was found in the sample which had been kept. This determination is recorded in the bottom line upon table 95a, where a sample of the Illinois river water taken at Averyville, August 17th, 1899 at
6:30 P. M., and examined August 18th, 1899, at 7:05 P.
8357 M., approximately 24 hours after the time of collection.
This abnormal condition will be considered more in detail farther along, when we discuss the conditions at Averyville.

Dissolved oxygen in the water of the Illinois river, at its mouth at Grafton: The series of determinations dissolved oxygen which appear in the tables 95a to 95g, show that during the period January 4th to June 27th, 1900, the percentage of saturation in the Illinois river water ranged from 43.1 to 95.7, the average being 76.47 per cent for the entire series of 141 shipped samples. As is seen in the date columns, the determinations were made upon samples shipped to the laboratory in usually about 24 hours after collection. The minimum 43.1 per cent, was found in the case of four samples collected May 16th, and examined May 18th. In no other case was less than 52.7 per cent found, and indeed, in but five other samples was less than 61 per cent dissolved oxygen found.

Dissolved oxygen in the waters of the Mississippi river at Grafton: A parallel series of determinations of dissolved oxygen in the waters of the Mississippi just above the mouth of the Illinois was made upon samples collected at the same time, that is, within a few minutes and shipped and examined under similar conditions. The details appear upon tables 95e and 95f,
8358 inclusive. The degree of saturation in these samples ranged from 55.78 per cent to 108.84 per cent, the average for the entire series of 127 samples being 82 per cent.

Comparison of the data obtained from these two series of shipped samples, shows that the waters of the Illinois contain 93.2 per cent of the quantity of dissolved oxygen found in the waters of the Mississippi.

Q. Will you explain what you mean by that?

A. I mean by that that in these shipped samples there was little more dissolved oxygen in those which came from the Mississippi river than was found in those which came from the Illinois river, the relation being as 92.2 in the Illinois to 100 in the Mississippi.

Q. What year was this?

A. This was the year 1900. Analyses made upon the spot (see tables 95c, 95d, and 95e) show that both the Illinois river water at Grafton and the Mississippi river water at Grafton frequently contain a greater proportion of dissolved oxygen than is required for saturation, but each of them also frequently contains less dissolved oxygen than the saturation figure required. In general it is true, that the waters of the Illinois do not retain their dissolved oxygen so long as do the waters
8359 of the Mississippi, that is, the dissolved oxygen diminishes more quickly and to a greater extent in the water of the Illinois than it does in the water of the Mississippi although the

difference between the two river waters in this respect is not very great as may be seen by a study of the data of the tables.

Q. Can you give any explanation of this difference?

A. Well, I can when it comes to a discussion of the significance of dissolved oxygen, which I understood we were to consider when we got through with the discussion of the data here on the tables.

Q. All right.

A. The upper Illinois: In the Illinois river at LaSalle just above the town upon August 16th, 1899, we found the water eighteen inches below the surface just saturated with dissolved oxygen, the actual figures being 100.12 per cent to 100.36 per cent in samples taken at different points across the stream.

A. Sample of the water taken at the same time but examined 24 hours later contained but 75.7 per cent of dissolved oxygen, while still another sample collected at the same time as the three above mentioned, but kept 41 hours, contained but 58 per cent of the amount required for saturation. The evidence would seem to show that although during sunshine, oxygen was being evolved by the vegetable life in the water
8360 with sufficient rapidity to keep the water saturated, yet
when the conditions were changed by placing the sample in the dark such action ceased, and the oxygen began rapidly to disappear.

Similar conditions were found with respect to the water of the Illinois and Michigan canal at La Salle. The water at the upper basin at La Salle was, before the opening of the sanitary canal, in better condition ordinarily, than was the water of the Illinois river at this point, for the reason that the canal above LaSalle was fed from the Fox river and other streams. The records with respect to the water in this place, as given in table 95a, show that the water in its original condition contained 102.42 per cent, while after standing 24 hours it was reduced to 62.26 per cent.

Upon August 17th, somewhat striking conditions were found at Henry. The samples were taken above the dam at 1:15 P. M. upon a bright day. The temperature of the water, 32 degrees C. being very nearly as high as that of the air, which in the shade was 34 degrees. A sample of the water taken one

inch below the surface, was found to contain considerably more than twice the amount of oxygen required for saturation, presuming of course, the saturation figure should be that for an equilibrium between the oxygen of the atmosphere and
8361 that dissolved in the water.

The water was full of minute vegetable organisms, and it had a very distinct, yellowish green tint. The temperature of the top inch of water was 32 degrees C., or 89.6 Fahrenheit. The quantities of dissolved oxygen found by the Levy method in this water were 220.9 per cent, and 211.4 per cent respectively. Samples taken at the same time and place, but at eighteen inches below the surface had a temperature of 28 degrees Centigrade, and were found by the Levy method to contain dissolved oxygen corresponding to 200 per cent of saturation, and 208.3 per cent of saturation respectively. While the determinations made upon the same samples by the Winkler method showed 208.35 per cent. A sample collected at the same time and kept until the next day, the analysis being made 24 hours after the time of collection, during which time the sample was kept in the dark, was found to contain 110.1 per cent of the saturation figure. At the same time and place a collection was also made at two feet from the bottom, or ten feet below the surface. At this depth also the water was found to be supersaturated but far less so than the water at the surface; it contained 129.1 per cent. These samples were all taken a short distance above the dam and it is probable that the water at two feet from the bottom was comparatively sluggish in motion, and the conditions of tem-
8362 perature and of illumination by sunlight were not the
same as those prevailing in the strata of water nearer to the surface. The dissolved oxygen in the water very near the bottom disappeared much more rapidly and was reduced far more proportionately than that in the water taken near the surface. The percentage remaining at the end of 24 hours being about 47.42 per cent. This difference as to retention of dissolved oxygen was undoubtedly due to a difference in either the Plankton or the other organic matters contained in the water in these two different stratas.

Averyville: Several visits were made to Averyville, just above Peoria, for the purpose of making determinations upon the spot, and some of these developed quite interesting results, as upon July 21st, 1899, the water eighteen inches below the surface was found late in the afternoon to contain 171 per cent of the saturation figure of dissolved oxygen and the water was still supersaturated with oxygen when samples which were kept in the dark were again examined 18 hours and 24 hours later, after the lapse of this time, the figure being 115 to 117 per cent respectively.

The quantity of dissolved oxygen in the samples collected at the same spot the following morning were found to be only
87.8 per cent, but during the morning it increased slightly
8363 to 95.6 per cent at 10:10, reaching 111.7 per cent at 12:20
P. M., and 114.3 per cent at 1:10 P. M. at which time the examinations were stopped by the necessity for catching a train. Samples collected at the same time were kept over for two days, and it was found that the quantity of dissolved oxygen had diminished in 48 hours from 114 per cent to from 38 to 40 per cent. (See in Illinois river, Averyville, July 22nd, 1899, at bottom of table 95a.)

On August 17th, late in the afternoon the quantity of dissolved oxygen found in the water at the depth of 18 inches at Averyville was 80.5 per cent, while the water coming from about two feet above the bottom in fourteen feet of water contained 74 per cent of the saturation figure. A sample of the water taken eighteen inches below the surface at 6:30 P. M. which was kept until the next day was found to contain a considerably higher quantity of dissolved oxygen than the sample which was examined at the time of collection. The determination on the spot gave 80.49 per cent, and that made 24 hours later gave 97.53 per cent. It may be that this is an error, but it is possible that in this case some more hardy oxygen-envolving organisms than usual were contained in the water, and that during the following day, which was excessively hot, light was not entirely
excluded from the sample; or the original content of
8364 oxygen may possibly have been quite different, for as
is evident from the records for the 19th, when this point was again visited, the water earlier in the afternoon was supersaturated.

Upon August the 19th at 12:30 p. m., a sample taken eighteen inches below the surface contained 184 per cent; another taken at the same time but three hours later contained slightly more than 200 per cent, and a sample collected at four o'clock contained 215 per cent. Another collected at 4:25 contained 215.7 per cent, while the samples of water collected one and one-half hours later at the same point and under the same conditions were found to contain 95.6 per cent, dissolved oxygen.

During the time that these examinations were made, the surface of the water was marked here, there and everywhere, with patches of blue-green scum the size of a man's hand, apparently consisting of masses of filamentous algae. The current was quite rapid and these patches were about two or three feet apart in various directions. The samples were taken under such conditions as to exclude these floating matters from the sample of water upon which the test was made. The sun was shining very brightly and the temperature was very high
8365 These examinations were made at the Averyville bridge
where the river is very narrow and the current rapid. Between this point and Henry, about 38 miles above, the river spreads out to a considerable width, forming a series of so-called pools, lakes or lagoons, in which the current is very sluggish. In these broad stretches the conditions of depth, spread of surface, temperature and rate of movement are in the summer season especially, favorable for the development of plant life and and the water consequently so teems with green and green-blue organisms that oxygen is evolved in great abundance, in fact may frequently be seen coming from the floating plants in streams of minute bubbles. During the middle of the day when the chemical activity of the sun's rays is at the maxium, the evolution of oxygen naturally will be at the maximum, and the water then becomes supersaturated but as the sun sinks towards the West the action slackens, and the excess of oxygen begins to disappear, partly perhaps by diffusion into the atmosphere, but undoubtedly in the main through absorption by the organic matters either living or dead, contained in the water, and in part by the cessation of the evolution of oxygen through the agents just referred to.

The water which was found to be supersaturated at Averyville, doubtless received its oxygen mainly at some distance above, and the rather sudden drop from 215 per cent to
8366 95.6 per cent was in all probability due to the fact that
a new body of water which in the late hours of the after-

noon had not been exposed to such vigorous action as prevailed earlier in the day began to reach the point of collection. This change may have also been due to the fact that as evening approached, the sun was in part obscured from the particular point at which these examinations were made, by dropping below the high wooded bluffs which line the west bank of the river in this vicinity.

Later in the year, that is upon October 16th, 1899, another series of examinations were made in Averyville, but at this time the conditions were entirely different. The quantity of dissolved oxygen reached but 74.5 per cent, to 77.5 per cent.

Examinations which were made during January, 1900, gave similar results to those mentioned for October, 1899.

Examinations made in June, 1900, showed figures which were considerably below those obtained in July and August of the preceding year. It is unfortunate that we did not have an opportunity to make determinations in 1900 upon the same dates as in 1899, for in June the season is not sufficiently advanced to bring about the conditions which are commonly encountered in the latter part of July and the middle of August.

8367 The results obtained in October, 1900, were practically identical with those obtained in October, 1899, which would seem to imply that the opening of the drainage channel has not materially changed the conditions with respect to dissolved oxygen at this point and for this season of the year.

Dissolved oxygen just below Peoria: A few examinations made at Wesley City have always shown that the water of the river at this point contains far less than the saturation quantity of dissolved oxygen, a result due of course to the fact that so much sewage is discharged into the river about two or three miles above. Somewhat similar conditions were found with respect to the water at Pekin. The effect of bright sunlight is strikingly shown by comparison of the figures obtained upon August 18th, in the middle of the morning with those obtained August 19th, late in the afternoon, the figures for the morning being 24 per cent; those for the afternoon averaging about 82 per cent.

Examinations of water collected early in the morning of August 19th at Havana, 30 miles below Pekin showed but about one-third as much dissolved oxygen as would correspond to the saturation figure, while later in the day determinations by both

the Levy and the Winkler method made at Copperas
8368 Creek dam and at Lancaster Landing, points between
Havana and Pekin, showed considerable excess of dissolved oxygen. The weather was hot, 100 degrees to 108 degrees Fahrenheit in the shade, and there was considerable plankton in the water, much of it appearing to consist of filamentous and other algae.

Dissolved oxygen in the water of the Drainage Canal: Several determinations were made of the dissolved oxygen of the waters of the Sanitary Canal itself. Upon August 13th, 1900, an examination was made of the water in the upper end of the sanitary canal at Kedzie Avenue. At 5:15 in the afternoon, a sample taken eighteen inches below the surface was found to contain 29 per cent, and a little further down the canal, that is at the Belt Line Bridge at 5:40 o'clock, it was found to contain 28.2 per cent. Upon June 29th, 1900, at five o'clock in the afternoon, this water just above the Bear Trap Dam at Lockport was found to contain 10.9 per cent of dissolved oxygen, while at 200 yards below the dam, after the water had been agitated with air in its escapes from the higher level of the drainage channel to the bed of the Desplaines river below, the aeration had been sufficient to bring the proportion of dissolved oxygen up to 55.5 per cent of the saturation figure. Upon August 14th,
1900, similar determinations showed, that the water above
8369 the dam contained 5.9, and that below the dam 70 per
cent. of dissolved oxygen.

At Joliet, examinations made upon June 30th, 1900, showed 27.8 per cent. of dissolved oxygen just above Dam No. 1, while just below the dam where the water has fallen 12 or 13 feet the percentage of dissolved oxygen was found to be 81.28.

In making these determinations, due care was exercised to prevent any minute bubbles of air being retained by the water which was made the subject of the examination. The entire pipette was filled with the water and was allowed to stand for a few minutes until such bubbles as were contained in the sample collected in the upper part of the pipette, and were allowed to escape.

The results obtained at Lockport and at Joliet show quite strikingly the effect of agitation of the water with air in falling over the dam.

A single determination made upon the water of the Fox river at Ottawa, August 20th, 1899, showed the water of this tributary to be quite supersatured. It contained 128.35 per cent. of dissolved oxygen. The water of the Illinois and Michigan Canal, just above Channahan was examined upon August
21st and was found to contain three per cent. of the
8370 saturation figure of dissolved oxygen. At this time there
was practically no water flowing in the bed of the upper Desplaines below Joliet, as at Joliet all of the flow both from the Desplaines river above and from the Illinois and Michigan canal was carried down the north bank of the river in the canal itself.

Adjourned until 10:00 a. m. following day, Wednesday, October 14th, 1903.

8371 10:00 A. M., Wednesday, October 14th, 1903.
Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ARTHUR W. PALMER,

resumed the stand for further direct-examination by Judge Springer and testified as follows:

THE WITNESS: I desire to call attention to two errors which are contained in the tables heretofore read in evidence by me, namely, in table 60 concluded, serial No. 8214, the entire analysis belongs in table 61 concluded, at the place indicated by serial No. 8215, since this sample of water was obtained not from the Illinois, but from the Mississippi river, and No. 8215 which is now in table 61 concluded, must be transferred to table 60 concluded, in the place of No. 8214, which has just been removed, and a correction of the chlorine stated for 8215 must be made. In reality it is 20 parts per million instead of 4 parts per million as recorded in table 61 concluded.

There may be other errors in the tables, but such as they are they are certainly very small. I have looked up some of them,
that is, have detected some of them, and doubtless there
8372 are others, but such as they are are certainly too small to
affect seriously any of the general conclusions or the

general averages. These corrections were by me made before the averages went to print, and the changes here made do not consequently affect the figures of averages in tables A to C, inclusive.

JUDGE SPRINGER: Counsel for defendants now desire to put in evidence certain graphic plates which were made by this witness and which exhibit in a compact form the results which are given in the tables numbered Table 1 to Table 80 inclusive.

Q. Professor, I hand you a paper which is designated Plate 1. Will you please state whether you prepared that plate or not, and if so, upon what ascertainments or chemical analyses you base it, and what is its significance. But first state whether this is a plate prepared by you?

A. It is.

Q. And is this plate based upon the averages contained in any of the tables that you put in evidence?

A. It is a representation of certain of the averages which appear in table A, which averages have been made from the detailed data of the tables 1 to 38 inclusive.

Q. You may now read the plate in evidence.

8373 MR. JEFFRIES: I object to the reading of the plate in evidence, or to the witness making any explanation or giving any evidence in connection therewith, for the reason that the same is incompetent, irrelevant and immaterial, and for the reason that it has reference to conditions that existed prior to the opening of the Chicago drainage canal and therefore can be neither relevant, competent or material.

I object to the witness reading the plate into the record or making any statements in connection therewith for the further reason that it is in part based upon certain analyses made of various tributaries of the Illinois river, which analyses and all evidence in relation thereto, is incompetent, irrelevant and immaterial, and samples of water so examined from the tributaries are not and were not of sufficient number to throw any light on the true condition of the water contained in the tributaries, and for the further reason that the samples of water were taken from tributaries without reference to the condition of the water in the rivers at all seasons of the year, and at all stages of the water, and without reference to the volume of water con-

tained and flowing down the tributaries during all parts of the
year, and I object to the reading of the plate into the record
and to the witness making any explanation in reference
8374 thereto for the further reason that the dates that the
samples of water were taken from the Illinois river, the
Mississippi and the Missouri and the dates of analyses are shown by the tables upon which the plate is based, and from which it is made, were such as not to be comparable and these samples were not taken with a view of determining the chemical condition of the water at all seasons of the year in question, and with reference to the condition of the water in flood times, low water times, in winter and in summer, by night and by day, and for the further reason that the samples so taken, because of time consumed in shipment and making analyses, were so changed chemically speaking as not in any way to characterize the true chemical condition or sanitary condition of the waters of the Illinois river at the points and at the times the samples were taken.

JUDGE SPRINGER: Counsel for defendants move to stirke out this objection for the reason that it goes to the weight of the testimony and not to its admissibility or competency.

MR. JEFFRIES: My position is that the samples were so taken without reference to temperature, without reference to day time and night, without reference to flood time and low water stages, without reference to winter and summer seasons, and at such times and such dates, and the analyses made at
variable times after the samples were taken, that renders
8375 any comparison therefrom entirely incompetent, and
therefore the plate is not admissible for any purpose.

JUDGE SPRINGER: I renew my motion to strike out for the same reasons stated before.

THE WITNESS: The plate is as follows:

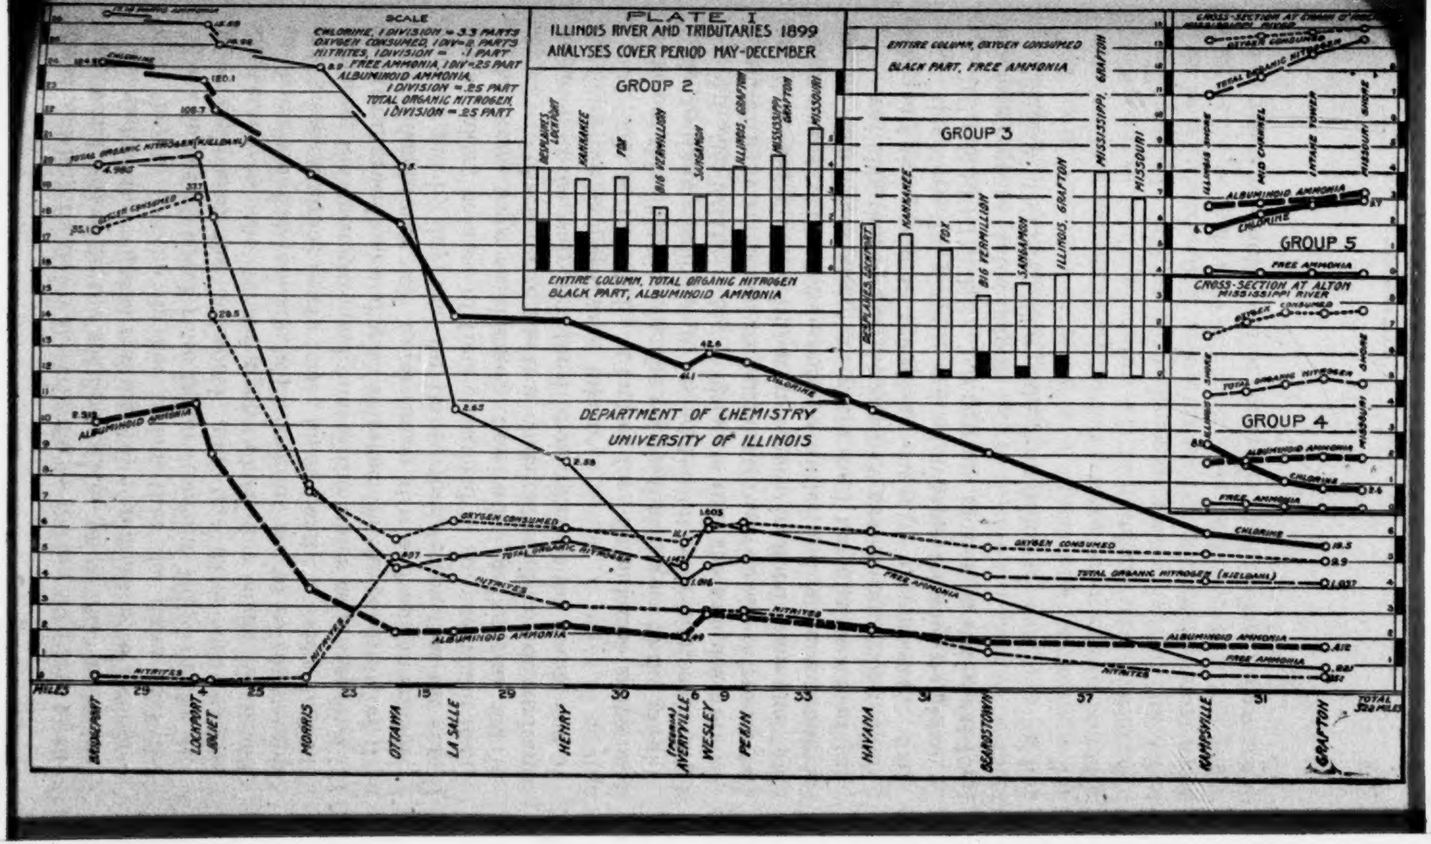

PLATE I
ILLINOIS RIVER AND TRIBUTARIES 1899
ANALYSES COVER PERIOD MAY-DECEMBER

DEPARTMENT OF CHEMISTRY
UNIVERSITY OF ILLINOIS

8377 MR. JEFFRIES: Let me ask a question. Professor, explain what the column "Average of" means on Table A, from which the plate in question was made?

A. I explained that in my testimony yesterday, and do so again at your request, to same effect, that the numbers in that column represent the numbers of samples of water analyzed as appears in the corresponding tables Nos. 1 to 38, inclusive, and which were considered in making up the general averages which appear in this table A.

MR. JEFFRIES: Now I move to strike out the plate, and all testimony in reference thereto, by this witness, for the reason that he has stated that column designated as "Average of" in the table of average results, for the year 1899, known as table A, and from which this plate in question was made, respresents the number of samples analyzed and from which a general average was struck, and it appearing from the able A that there was an average made upon 29 samples of water examined from the Kankakee river at Wilmington, 32 samples of water from the Big Vermillion at LaSalle, and 23 samples from the Sangamon river at Chandlersville, while there is no evidence so far introduced, showing that any such number of samples of water were taken from these rivers at these places, and no evidence showing that any such number of samples have ever been examined 8378 chemically; no evidence showing the manner in which the 23 samples in the one instance, the 32 samples in another instance, and the 29 samples in another instance, were taken; no evidence showing the point in the river from which they were taken, and therefore the plate does not accurately characterize and portray the facts that have been shown in evidence, in reference to conditions in the tributaries of the Illinois river in 1899, and therefore such results are not comparable with each other, or comparable with any conditions that exist or that might have existed on the Illinois river during that period.

JUDGE SPRINGER: I move to strike out this motion for the reason that it is principally argumentative, and in so far as it applies in any way to the matter under consideration, it goes to the weight of the evidence and not to its admissibility or competency.

Q. Proceed with your explanation of the plate, professor.

A. Explanation of Plate 1: I identify plate 1 as a chart which I prepared, to show graphically, some of the results which are given in detail in the tables 1 to 80 inclusive, and the averages which are shown in table A.

Q. Heretofore read in evidence in this case?

A. Yes. This particular plate No. 1, shows graphically
8379 the proportions of chlorine, oxygen consumed, nitrites,
free ammonia, albuminoid ammonia, and total organic nitrogen as determined by my analyses, set forth in detail in tables 1 to 80 inclusive, and particularly as shown in the form of averages in table A.

In order that the significance of the figures of table A, as shown graphically by means of the curves and columns of plate 1, may be fairly understood, I will as I proceed, state briefly the general significance which pertains to each constituent there represented, as we proceed with the discussion of the plate.

First, the chlorine. This substance is contained in water in combination with various basic elements, but chiefly in the form of sodium chloride or common salt. Chlorides occur in very small quantities in all soils, and hence are present in small proportions in the waters of streams, ponds, lakes and so on, in their natural condition, and in greater quantity are found also in wells, particularly in many artesian wells, and in salt springs. Most animal matters, and especially various animal secretions, contain more or less chlorides, and chlorides are constant in considerable constituents of sewage. In the sewage they are derived not only from the various animal secretions and particularly the urine contributed to sewage, but also are intro-
8380 duced in various manufacturing wastes, as the wastes
from soap factories, packing houses and so on. They are also contained in kitchen wastes, being derived from the liquids which have been in contact with food during the preparation of foods for the table. The only natural causes of change in the proportions of chlorine aside from such concentration as may result from long continued hot weather during the season of minimum flow, would be its decrease by dilution with waters which contain less, or its increase by mixing with waters and other liquids as sewage, and so on, which contain more. The chlorine introduced into streams in the form of chlorides,

remains unchanged—(if it were at any time introduced in other forms it might change, but it is not ordinarily so introduced). That is, is not in any way removed, absorbed or destroyed, but finds its way finally into the sea into which the stream or streams finally discharge. The determination of the proportion of chlorine consequently is an index to the total quantities of chlorides introduced into the stream from watever source, above the point at which the determination in question is made.

Referring now to the curve for chlorine upon the plate, we note that a very large proportion, namely 124.2 parts per million, was contained in the water of the Illinois and Michigan
8381 Canal at Bridgeport, on the average for the period, May
to December, inclusive, 1899. This period it should be understood is referred to throughout, in the discussion of Plate No. 1. The proportions of chlorine at Lockport and Joliet, respectively, 29 and 33 miles below Bridgeport, respectively, are smaller than the proportion at Bridgeport. The reduction in proportion at Lockport being due to slight dilution along the course of the Illinois and Michigan Canal; that at Joliet being due to the dilution effected by mixing of the waters of the Desplaines river with the discharges from the Illinois and Michigan canal, just above the point at which the Joliet samples were taken. From this point on down to Peoria there is shown continuous and considerable decrease in the proportions of chlorine. The decrease between Joliet and Morris, 25 miles below, due to the introduction of the discharges of various small streams into the Desplaines, but mainly due to the introduction of the waters of the Kankakee river, which latter was found for this period to contain on the average, 3.9 parts of chlorine per million. Below Morris there are small streams discharging water into the Illinois, which brings about a reduction in the proportion on the way to Ottawa. At Ottawa the discharge of the Fox river brings about a very considerable reduction in the proportions of the chlorine, so that at LaSalle the proportion is 47.3, as
8382 against 59.4, the proportion contained at Ottawa. The
Fox river at Ottawa during this period containing on the average 5.8 parts of chlorine per million. There is but slight dilution, as indicated by reduction of chlorine, between LaSalle and Henry, but beyond Henry again, a notable decrease in the

proportion of chlorine occurs, to Averyville, where the proportion is 41.1 parts per million. The decrease resulting from the dilution effected by the discharges of various small streams, and in part by the underground flow of land water into the river. This underground flow is known to be considerable along the entire stretch of the Illinois river between LaSalle and Beardstown, and is particularly considerable between Peoria and Havana, and in times of low water may have quite an appreciable effect in diluting the waters in the stream, an effect which of course was more considerable before the flow and the initial dilution were increased by the inflow of lake water secured by the opening of the Chicago main drainage canal in January, 1900. The increase of chlorine between Averyville and Wesley city resulted from the contribution of Peoria's sewage to the river, and in small part probably was due to the inflow of the water of certain saline artesian wells, and springs. From this point,
that is Wesley City just below Peoria, there was a con-
.8383 tinuous and considerable diminution in the proportions
of chlorine at all points down to the mouth of the river at Grafton, and the final discharge into the Mississippi river contained chlorine in the proportion of 18.5 parts per million.

The next curve which we may consider represents the oxygen consumed. Oxygen consumed is the quantity of oxygen required for the burning of the organic matters contained in the water, or rather the quantity of oxygen required for combination with and oxidation of those organic matters contained in the water which are readily affected by the process used in these determinations, for it is well known that not all of the organic matters are affected or at least are not completely oxidized by the chemical processes employed. It is evident from the curves which merely represent the figures in the table of averages in table A, that the organic matters which at Lockport required a great deal of oxygen for their consumption, namely, 37.7 parts per million, were so affected by dilution and natural oxidation, as to appear in much smaller proportions at Morris and at Ottawa. A notable increase occurs between Ottawa and LaSalle, but the organic matters then below LaSalle diminish in proportion until we reach Averyville, where the proportion was 11.1 parts per million. Below Averyville there occurs an

increase until we pass Pekin, and from there on down to
8384 the mouth of the river at Grafton, occurs a gradual
but definite diminution, the quantity of oxygen consumed by the waters as they pass from the Illinois into the Mississippi being 9.9 parts per million.

Free ammonia, or saline ammonia as it is variously designated, is naturally present in small proportions in surface waters, being introduced into them by the washings of the air by the rain, and from surface soils, by the rain water, which in times of storm flow in part over the surface to the streams. It is contained in comparatively great quantity in fresh sewage or sewage which is in the first stages of putrefaction. In the sewage it has come in part from the sanitary wastes of the household, including the discharges from human beings, but comes also from other household wastes, and from the discharges of other animals. It comes in part from discharges of manufacturing wastes and industrial wastes of various sorts, including stock yards wastes, refuse from gas works, and the decomposition products of the same and so on, and is produced by the putrefactive changes to which organic matters from all these sources are naturally susceptible.

The large proportions of nitrogen as free ammonia contained in the waters of the canal at Bridgeport and Lockport,
respectively, are represented at the left hand of the table
8385 and by the figures 17.16 and 15.58 which appear in table
A of Averages. The diminution in proportion between Lockport and Joliet is due to dilution by the waters of the Desplaines, and between Joliet and Morris, to the dilution referred to above under the discussion of chlorine and oxygen consumed, namely, dilution effected mainly by the introduction of the waters of the Kanakee, and is in part effected by the natural decomposition or changes to which this substance is subject in streams and other surface waters. Between Ottawa and LaSalle, there is a very great diminution, namely from five parts per million to 2.65 parts per million. This diminution being effected in part by dilution with the waters of the Fox river and other but minor tributary streams, and in part due to nitrification which takes place vigorously in the stretch of stream between Ottawa and LaSalle, and it may in part be due also to assimila-

tion by the plant life, which is abundant in this part of the river, and in part due to its conversion into free nitrogen which escapes in part into the air. On the other hand, there may at times be a tendency toward an increase of the proportions of free ammonia as a result of the de-oxidation of nitrates and nitrites, which takes place when these substances in water are in contact with various organic matters.

8386 Between LaSalle and Henry there is further diminution in the proportions of free ammonia notwithstanding the fact that just below LaSalle the sewage of LaSalle is, by the final discharge of the Illinois and Michigan canal, introduced into the Illinois river, and that the sewage and wastes of Peru also are introduced at this point.

Between Henry and Averyville there takes place a more considerable diminution in the proportions of free ammonia, this being undoubtedly due to the natural destruction of ammonia or its oxidation into nitrates and nitrites or its assimilation by the plant life of the river, or to all of these causes together.

Now I notice a mistake in the figure given upon this plate. The figure in the table of averages is correct, and the curve is drawn to proportion all right, but the figure there above Henry, in the plate is put 2.56 and it should be 2.156—perhaps a minor correction, but one it is well to have made.

Beyond Averyville there is an increase in the free ammonia to Wesley City, a slight further increase to Pekin, and from there on down to the mouth of the river, continuous decrease—slight it is true—until we reach Havana, but beyond Havana more considerable in proportion until we reach Kampsville, 8387 where the proportion is only slightly greater than that contained in the water as it is discharged into the Mississippi at Grafton, 31 miles below, where the proportion is .221 parts per million.

MR. JEFFRIES: That is at Grafton?

A. At Grafton, yes.

Nitrites: Nitrites as contained in surface waters may be derived from the washings of the air by the rain; the leachings from the surface soils with which the fallen rain has been in contact on its way to the surface streams, which discharge it into ponds or rivers, and is also produced by the oxidation of nitrogenous organic matters derived from these or other sources and contained in the surface water, be it that of ponds or streams.

The nitrites constitute a stage or represent a stage in the series of decomposition which convert organic matters finally into the comporatively unobjectionable mineral matters which are chiefly carbonic acid and nitrates. The comparatively small proportion of nitrites in the upper river down to the neighborhood of Morris shows that this second stage of natural purification is to this point but beginning, but the great increase below Morris witnesses to the fact that from here on this highly important feature of nature's purification processes is efficiently active. 8388 The gradual diminution of the nitrites on the way down the river from Ottawa to Averyville. would indicate a gradual progressive exhaustion of the food supply for the organisms which are responsible for this oxidation and thus serves as evidence that the purification is proceeding. The proportions of nitrites contained in the water may at times also be increased by the reduction of nitrates, which reduction at times proceeds beyond this stage, and brings about the liberation of nitrogen in the form of nitrogen gas, the element, or may proceed further to the stage of ammonia, and so increase the proportion of the latter. The nitrites decrease in proportions from Pekin on down to Grafton, and this indicates the considerable improvement in the sanitary condition of the water during its pasage from Pekin to the point of discharge into the Mississippi river at Grafton.

Total organic nitrogen: This determination, made by the Kjel Dahl process, represents the total proportions of nitrogen contained in the water in combination in organic matters. The nitrogenous organic matters are contained in all soils in some quantity, but they are the most significant and constant constituents, of sewage, and include all sorts of animal refuse, tissues, fecal matters, constituents of the urine, household 8389 wastes and manufacturing wastes of various sorts, particularly those of animal origin, but also those of vegetable origin. Nitrogenous organic matters too, are essential constituents of all living things, great or microscopic, both vegetable and animal. It is substances of this class in part

which serve as the nutrients upon which bacteria thrive and multiply. The proportions of nitrogen as total organic nitrogen, that is the total nitrogen contained in organic matters, are shown by the figures of table A, and represented by the line upon plate 1 as being very considerable in the waters of the Illinois and Michigan canal, both at Bridgeport and at Lockport, the quantity diminishing between Lockport and Joliet, diminishing again very considerably between Joliet and Morris, and again diminishing on the way to Ottawa, but beyond Ottawa increasing in proportion on the way to LaSalle and Henry, below which there is again a decrease to Averyville. The decrease between Joliet and Ottawa is party due to dilution by the introduction of the waters of various tributaries, but in very large part is due to the natural destruction of these organic matters, and their conversion into more innocuous forms, partly into mineral matters, partly into the organic matters of the vegetation of the river. The increase on the way to LaSalle and Henry is due
to the introduction of sewage by means of the Big Ver-
8390 million river, and the sewage of LaSalle and of Peru.
The increase below Averyville on the way to Wesley City, is due to the introduction of Peoria's sewage and refuse. Below this point, there occurs at first slight, but then a more considerable decrease in the quantities of total organic nitrogen on the way down to Beardstown, below which point there is a very slight decrease down to the mouth, where the proportion contained in the water as it is discharged into the Mississippi was during this period 1.037 parts per million.

Albuminoid Ammonia: The albuminoid ammonia varies somewhat in conformity with the variations of the total organic nitrogen, although the quantity is but from 40 to 50 per cent. that of the latter. Its significance is similar to that of the total organic nitrogen, but the total organic nitrogen represents all of the nitrogen that is contained in the organic matters, that is as constituting part of the tissues, living or dead, as well as various products of vital activities of living organisms, while the albuminoid ammonia represents only the nitrogen. Of such part, about one-half of these substances, as is comparatively easily affected by the chemicals and processes used in the albuminoid ammonia determination.

8391 Comparison of the waters of the Illinois with those of its tributaries and those of the Mississippi and the Missouri are made in groups 2 and 3 of Plate 1. The various columns show the comparative proportions of total organic nitrogen, albuminoid ammonia and free ammonia contained in, and the oxygen consumed by, the waters of the more important tributaries of the Illinois river, the waters of the Mississippi river above the mouth of the Illinois and the waters of the Missouri river just above its mouth. The columns in all cases representing the figures given in table A. It appears that during this period the waters of the Illinois at its mouth at Grafton, contained more free ammonia than those of the Mississippi and the Missouri and considerably more than those of its tributaries, except the Big Vermillion, the Illinois and Michigan canal not being considered. On the other hand, the columns show that the waters of the Mississippi and the Missouri contain considerably more total organic nitrogen and albuminoid matters than did the waters of the Illinois, while the oxygen consumed by the waters of these two streams was nearly twice as great as that consumed by the water of the Illinois. In these respects, too, the columns show that the water of the Illinois river at its mouth compares favorably with the waters of its several tributaries.

8392 The Mississippi at Alton: The curves of group 4, plate 1, referring to the cross-section of the Mississippi river at Alton represent the averages of analyses of samples of water taken at the five points across the Mississippi at Alton, about sixteen miles below the mouth of the Illinois. It is evident from the consideration of the data, tables 23 to 27, inclusive, and the averages of table A, and as graphically shown by the curves of plate 1, that the waters of the Illinois do not mix thoroughly with the waters of the Mississippi, but chiefly pass down along the Illinois shore, and that the proportions of organic matters contained in the Mississippi river water are greater than the proportions of the same substances contained in the Illinois river water. The chlorine and ammonia, on the other hand, being higher in the Illinois river water at Grafton than in the waters of the Mississippi river at Alton or at Grafton.

The Mississippi at chain of rocks, or Mitchel:

The waters of the Missouri river during the period here considered, did not average so high in chlorine as did the waters of the Illinois, but they contain an enormous amount of suspended matters, and notably greater quantities of various objectionable organic matters. From the data of tables 28 to 31 and the averages of Table A, exhibited in group 5, Plate
8393 1, it would seem that at the chain of rocks the waters passing down the west bank and beside the intake tower, consist mainly of Missouri river water and contain much larger proportions of organic matters than do the waters of the Illinois.

Further comparisons: A consideration of the analyses of the individual samples given in tables 28 to 31 shows that the proportions of the nitrogenous organic matters never during the given period were so great in the Illinois river water as they were in the Missouri, and that the minimum proportion of these matters in the Mississippi and in the Missouri river water never reached quite the low point that they did in the water of the Illinois river at Grafton.

The general conclusion from the consideration of these data, which, however, it must be remembered cover simply the period from the beginning of May, 1899, to December 31st, 1899, is that the water discharged from the Illinois river is in these respects in purer condition than the water of the Mississippi river just above Grafton, or the water of the Missouri river at Fort Bellefontaine, or West Alton, and that it is in most respects quite similar to the waters of the larger tributaries of the Illinois. Table G gives the specific data.

8394 Q. Professor, I now hand you papers which are designated as plates II and III. State whether those were prepared by you and what they were based upon?

A. I prepared plates II and III and they are based upon some of the averages which appear in table B.

Q. Heretofore read in evidence?

A. Heretofore read in evidence, and which shows the results of analyses of the water taken at different points in the Illinois river and its tributary streams, the Mississippi and Missouri rivers during the period January 1st to October 1st, or thereabouts, in 1900, the details of which appear in tables 39 to 80 inclusive.

JUDGE SPRINGER: I now offer in evidence these plates II and III and ask the witness to read them as part of his testimony.

MR. JEFFRIES: I object to the witness reading the plates into the record for the reasons stated in my objection to the reading of plate I, except that part of the objection which refers to the samples of water and the analyses thereof having been made in the year 1899, the year prior to the opening of the canal.

I object to their being read into the record for the further reason that they are not comparable with each other and for the further reason that the witness has stated that they are 8395 made only from some of the averages, and not all of the averages or analyses that were taken or made from samples of water taken from the river at various points, and for the further reason that the table of averages does not contain the same number of samples averaged. Therefore the plates are not comparable with each other, nor comparable with the actual chemical condition of the Illinois river at the points samples were taken and at the time they were taken, and are not representative of the water of the Illinois river at the time the samples were taken and at the places they were taken.

JUDGE SPRINGER: Counsel for defendants submits the same motion as was made in reference to the objection to plate I.

THE WITNESS: Plates II and III are as follows:

8398 JUDGE SPRINGER: Now will you please explain this table on the significance of these lines?

A. Plate II is similar to Plate 1, in that it shows the proportions of various significant constituents contained in the waters of the Illinois and its tributaries, and the Mississippi at Grafton, Alton and chain of rocks, and the Missouri at Fort Bellefontaine, for the period January 1st, to October 1st, 1900. That is, the nine months immediately subsequent to the opening of the Chicago main drainage channel. The effect of the dilution of the Chicago sewage with the lake water before discharging it into the Desplaines and the Illinois is shown by the analyses made during the year 1900. The data of these analyses appear in tables 39 to 80 inclusive, and the averages are brought together in table B.

The features of plate II are similar to those of plate I, but differ in that the proportions of the various constituents are not the same. These conditions being caused in the main so far as the samples from the Illinois river are concerned by the dilution effected by the opening of the Chicago main drainage channel. Discussion of this plate in detail is hardly necessary or especially profitable for the reason that the period covered is not the same as that covered by the figures and lines of plate I, and for the further reason that a consideration of all such data as are included in the representations of plate II, which
8399 are strictly comporable with the figures and lines of plate I are discussed and are represented by columns and curves in plates which are shortly to be considered.

It is a well known fact that the waters of streams vary greatly at different seasons, both as to the volume of water and the content and nature of substances carried by the water. These seasonable variations are particularly important in the cases of some of the streams of the Mississippi valley and especially so for the Illinois, the Missouri and the Mississippi. Although the entire series of analyses for the year 1900 does not correspond as to the time and season with the entire series of analyses for the year 1899. These two seasons overlapped during the summer months, namely, the four months, June, July, August and September, during which period the most important physical features are the comparatively small volume of flow and

the comparatively high temperature, not only of the atmosphere but of the water itself, features which are especially important with reference to the Illinois river. In consequence of this overlapping, the data during this period for the two different years, namely, June, July, August and September, 1899, and June, July, August and September, 1900, are fairly and reasonably comparable with each other. For the purpose of
8400 making this comparison, I have prepared averages of the data of the Illinois made during June, July, August and September, 1899, that is before the opening of the main drainage channel and similar averages from data obtained from analyses made during the same four months in 1900 or immediately after the opening of the main drainage channel. The data appear in detail in tables 1 to 80 inclusive, and the particular averages in question appear in tables C and D respectively.

Q. Which have been read in evidence by you?

A. Yes sir.

Adjourned until 2:00 p. m. same day, Oct. 14, 1903.

8401 2:00 P. M., Wednesday, October 14th, 1903.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ARTHUR W. PALMER,

resumed the stand for further direct examination by Judge Springer and testified as follows:

Q. Professor, I hand you a paper which is designated as plate IV. Please state whether that plate was made by you and if so where you obtained the data from which it was made?

A. Plate IV was made by me. The data represented upon it appear in the form of averages in tables C and D which were heretofore read in evidence, and the details from which the averages were made appear in tables 1 to 80 inclusive, which tables have heretofore been read in evidence.

JUDGE SPRINGER: I offer the plate in evidence and the witness will please read it as a part of his testimony.

MR. JEFFRIES: To the reading of the plate into the record I object for the same reasons stated in my objection to the reading of plates II and III, and for the further reason 8402 that the plate being now offered in evidence, being based upon tables C. and D. no comparison can be drawn with reference to the chemical constituents in the water that would be relevant in this case, for the reason that table C purports to represent the chemical constituents contained in the water of the Illinois river prior to the opening of the Chicago drainage canal, and table D purports to represent the condition of the water in the Illinois river subsequent to the opening of the canal and no comparisons that would be drawn from these tables would be comparable with each other, or with the conditions prior to the opening of the canal, because of the influence of the addition of water to the volume of water in the Illinois river, and by reason of the increased flow of the water in the Illinois river, and it would therefore have no bearing upon the sanitary condition of the water in the Illinois river as it has existed and will exist, since the opening of the drainage canal.

JUDGE SPRINGER: Counsel for defendants move to strike out this objection for the reason that it goes to the weight of the evidence and not as to its admissibility or competency.

A. The plate when copied into the record is as follows:

8404 Q. JUDGE SPRINGER: Now will you please explain what this plate illustrates?

MR. JEFFRIES: We object to any statement being made by this witness with reference to what the table purports to contain or set forth, for the same reasons stated in our objection to the copying of the plate into the record.

A. Plate IV is one of a set running from IV to XV, inclusive, which have been prepared for the purpose of representing graphically the average proportions of some of the more significant constituents of the waters of the Illinois river, its tributaries, the Mississippi and the Missouri, as they appear in the tables of averages C and D, representing the detailed analyses of tables 1 to 80 inclusive, covering the period June, July, August and September, 1899, the year prior to the opening of the Chicago main drainage channel, and the same period, that is, June, July, August and September, 1900, the year subsequent to the opening of the Chicago main drainage channel.

In order that the situation and the full significance of the data which are represented by the plates be realized, reference should be made to the statement of the reasons for selecting the various points at which the collections of samples were made and to the map which shows the relative situations of these points of collection—

8405 JUDGE SPRINGER: Counsel for defendants state that they will put in such a map as a subsequent part of the proceedings.

A. (Continued). In each plate of this set, IV to XV inclusive, there are two sets of curves or two sets of columns, one set representing the data for the summer of 1899 and the other representing the data for the summer of 1900. By following the various lines of the curve, and the proportions of the various constituents which they represent, it is made evident that the conditions in the river have changed considerably since the opening of the main drainage channel.

The portions of the curves and sets of columns at the left hand of each plate representing the conditions prevailing between Chicago and Lockport are of course modified more greatly than the other parts of the curves for the reason that until January, 1900, it was the old or Illinois and Michigan canal only

which carried the discharge of Chicago sewage into the Desplaines river valley, while since the opening of the drainage channel the sanitary canal itself carries not merely undiluted sewage and stock yards drainage, but a very large proportion of diluting lake water. Inasmuch as the Illinois and Michigan canal is still mainly fed from a fork of the south branch, which is not yet flushed with lake water, we find that the pro-
8406 portions of the various constituents are still excessive in
the waters of the old or Illinois and Michigan canal, both at Bridgeport and at Lockport. It is to be remembered that the discharge through the Illinois and Michigan canal is now much less than it was formerly, for since the opening of the drainage channel the old canal is used chiefly for transportation and not particularly as a sewer, and the pumps at Bridgeport are supposed to raise only such fluid as is required to maintain a serviceable depth for commerce. The average flow in the Illinois and Michigan canal prior to 1900 was from 35,000 to 36,000 cubic feet per minute. In 1900 it varied during the year, but the average was 26,700 cubic feet a minute. In 1901, the pumps were in operation only during seven months, beginning the latter part of April and reaching to the latter part of November. During this period of seven months, the average rate at which liquids were raised from the south fork of the Illinois and Michigan canal was 23,000 cubic feet per minute; the average for the entire year, which is not a true average for the time of operation, however, being 13,800 cubic feet per minute. The figures of tables Nos. 40 and 41 in which the data of analyses of samples from the Illinois and Michigan canal at Bridgeport and Lockport, for the year 1900, are set forth, reveal occasional
8407 variations of considerable magnitude. These variations
are chiefly due to the fact that the pumps at Bridgeport which feed the Illinois and Michigan canal are situated but a few rods within the mouth of the south fork and that the diluted sewage which, on its way through the south branch to the drainage channel, passes the mouth of the south fork, sometimes enters a short distance within the mouth and is thence pumped into the old canal. The short duration of such occasional conditions during which comporatively dilute sewage is pumped

into the Illinois and Michigan canal, accounts for the fact that the variations are less frequent and less considerable at Lockport, 29 miles below, for the reason that on the way the mixing of the more concentrated sewage ordinarily raised, and the more dilute sewage occasionally introduced by the pumps, is more or less perfected.

At Joliet where the discharges through the two canals and that from the upper Desplaines river have come together, there is frequent and considerable variation in the proportions of organic matter and other impurities contained in the waters of the Desplaines river, partly in consequence of variations in the flow of water from the Illinois and Michigan canal through the use of locks, partly from occasional closing of the gates at the
Bear Trap dam, thus shutting off or reducing the flow
8408 of the more dilute sewage from the drainage channel. The
accumulation of sewage in the Chicago river, which follows a stoppage or reduction of the flow through the drainage channel is another cause of variation, for when the gates are again opened the sewage discharged is for a time necessarily less dilute than it would otherwise have been. The variations at Joliet results in large part also from incomplete commingling of the waters, for the discharge from the old canal entering by the south or east bank at Lockport and at Joliet generally passes down beside that bank for some considerable distance, but at times when the flow from the drainage channel is reduced, it often extends further out into the stream or possibly may entirely cross the river bed. The variations which appear in table 44 are largely due to the facts just above considered.

Upon plate IV, there is shown, first, general curves representing the proportions of chlorine and of nitrogen as albuminoid ammonia in the waters of the Desplaines and the Illinois rivers at different points between Chicago and the mouth of the river at Grafton. For the purposes of this study the Illinois and Michigan canal and the sanitary canal are both regarded as being part of the one system which includes these canals,
the Desplaines river and the Illinois river stretching from
8409 Chicago to the Mississippi at Grafton. Comparison of the
two curves representing the chlorine shows a much more

considerable diminution of the proportions or chlorine contained in the water flowing through the bed of the Desplaines river at Joliet, in 1900 than in 1899. This is obviously due to the dilution of Chicago sewage with lake water which passes through the drainage channel. The continuous diminution in content of chlorine between Bridgeport—(in both years, following the Illinois and Michigan canal as far as Joliet)—and the mouth of the river at Grafton, is of course due merely to dilution. The average quantity of chlorine contained in the natural surface waters of the regions in question has ranged from two to three parts as in the water of Lake Michigan, to as much as five or six parts as frequently found in the waters of such streams as the Fox, the Kankakee, and the Sangamon. The waters which pass through the drainage canal contain a considerably smaller portion of chlorine than is contained in the waters passing through the Desplaines and Illinois river valley, for the reason already noted that the sewage carried by the Illinois and Michigan canal, and discharged by it into the Desplaines river at Lockport, and just above Joliet, is still very concentrated. Moreover, in and about Lockport and Joliet
8410 there are various saline artesian wells. There are sewers
and manufacturing establishments which discharge into the old canal or the river between the collecting point at Lockport and that at Joliet. From Joliet down, the river there is a slight fall in chlorine for 1900 as we reach Morris, and the subsequent apparent increase in the content of chlorine at Ottawa, notwithstanding the inflow of the waters of the Kankakee above Morris, are in some measure misleading, and untrustworthy, for the mixing of the two streams is at these points still incomplete, as subsequent work has shown, and to the incomplete mixing of the main body of water from the drainage channel with the waters of the various tributaries is due many of the variations in both directions which appear in the results for 1900 for the several points between and including Joliet and Ottawa.

Various cross-section determinations made at LaSalle, Averyville and Grafton have shown that at these several points the mixing is complete. Particularly at Averyville and Grafton, which we may regard as critical points, determinations of

chlorine in samples taken at a number of points across the stream have invariably shown that in these localities there is no difference in the chlorine content of the water anywhere between the two banks. At the mouth where the Illinois discharges into the Mississippi river, this water contains less
8411 chlorine than is found in it anywhere between that point
and Chicago, except in the sanitary canal itself. The proportion contained in the water at the mouth of the river in 1900 was very slightly greater than that contained during the corresponding time in 1899.

The curves representing the nitrogen as albuminoid ammonia show for 1899 a very rapid diminution in quantity as we pass from Bridgeport down the stream to Ottawa. Beyond Ottawa there is a notable increase, reaching the maximum at Henry but beyond that point there occurs a considerable diminution to Averyville or Peoria. Below Averyville, that is, at Wesley City and Pekin the quantities of nitrogen as albuminoid ammonia were greatly increased as a result of the discharge of sewage and wastes from distilleries, cattle sheds glucose works and such plants at Peoria and Pekin. Below Pekin again there is a slight but constant diminution until we reach the mouth of the river at Grafton. The curve for 1900 shows that there were much smaller quantities of albuminoid matters contained in the waters of the sanitary canal and in the waters of the Desplaines river at Joliet, and as we proceed down the stream from Joliet there is a decrease which reaches the limit at Ottawa. Beyond Ottawa the albuminoid nitrogen increases until Henry is
reached, beyond which point it diminished to Averyville.
8412 A slight increase occurred as we passed from Averyville
to Wesley, and Pekin and so on to Havana. Beyond Havana there is a gradual but continuous diminution until at the mouth of the river at Grarfton the proportion of albuminoid nitrogen contained in the water discharged from the Illinois into the Mississippi was notably less in 1900 than it was in the year 1899.

Comparison of the Illinois with the Mississippi and Missouri, group 2 on plate IV, represents first, comparison of the chlorine contained in the waters of the Illinois as it discharges into the Mississippi at Grafton, for the summer months of 1899 and for the summer months of 1900—

MR. JEFFRIES: I object to the witness making any comparisons or giving any testimony with reference to the chemical constituents of the water flowing down the Missouri river and the Mississippi river above Grafton, for the reason that the witness has not sufficiently qualified himself in evidence with the source of his information of those streams and for the further reason that the testimony is incompetent, irrelevant and immaterial, having no bearing upon the issues involved in this case and not being the subject at issue in this controversy.

JUDGE SPRINGER: I move to strike out the objection 8413 for the reasons stated in my motion to strike out the previous objections to these plates.

Q. Proceed, professor.

A. The proportions are stated in tables C and D, and represented in plate IV by the two columns at the lower right hand corner. Mere inspection of these columns is sufficient to show the relation of these proportions and to make manifest the slight difference as to chlorine content in the waters of the Illinois at its mouth between these two years.

Second, a comparison of the chlorine contained in the Mississippi above the mouth of the Illinois for like periods in 1899 and 1900. This is shown by the two columns next to the left of those referring to the Illinois river water. Inspection of the figures in the tables make manifest,—and the two columns in the plate show graphically the differences as to chlorine content in the Mississippi river water between these two years, and show that the proportion of chlorine in the Mississippi river water during this period in 1900 was considerably greater than during the similar period of 1899. This difference as to chlorine content between the two years was due doubtless to the fact that the water in the upper Mississippi river was at a lower stage during the summer of 1900 than it was during the 8414 summer of 1899.

Upon plate XVII which will be hereinafter introduced in evidence, the stages of water in the Mississippi river for the years 1899 and 1900 are represented.

Third, a comparison of the chlorine contained in the waters of the Missouri river near the mouth for the same periods. The figures in tables C and D show that the waters of the Missouri river contained a much higher proportion of chlorine during the summer of 1900 than during the corresponding season of 1899, but it must be noted that the period covered in 1899 is somewhat shorter than that for 1900, as in the earlier year the collections from the Missouri began July 10. The facts as represented in the tables of averages are shown in the plate by the columns labeled "Missouri" and serve to represent the considerable difference between the proportions for these two periods.

Fourth: Comparison of the content of albuminoid nitrogen in the Illinois river for 1899 and 1900, referred to in the general statement above, is shown graphically in this group, and these differences appear to the eye at once upon inspection of the columns.

Fifth: Comparison of the content of nitrogen as albuminoid ammonia in the water of the Mississippi river above the mouth of the Illinois. The second set of columns under the title
8415 "Nitrogen as Albuminoid ammonia" shows a slightly smaller proportion contained in the water of the Mississippi for 1900 than was contained during the same period of 1899, and shows further that there was considerably more albuminoid nitrogen in the waters of the Mississippi river during each of these periods,—that is both 1899 and 1900, than was contained in the waters of the Illinois river in either of the seasons in question.

Sixth: Comparison of the content of nitrogen as albuminoid ammonia in the waters of the Missouri. The figures which appear in tables C and D, show that during the summer of 1900 the proportion was greater than during the summer of 1899, and shows further that more than twice as much albuminoid ammonia or albuminous substances was contained in the water of the Missouri river in each of these years as was contained in the water of the Illinois river at Grafton and very considerably more than was contained in the waters of the Mississippi river. These facts as they appear in the tables of the averages, C and D, being represented graphically by the two columns at the left hand of the group 2, in plate IV.

Cross section of the Mississippi at Alton and at Mitchell, or chain of rocks, Group 3 on plate IV, represents the content of chlorine and of nitrogen as albuminoid ammonia in the waters
of the Mississippi river at four points across the stream
8416 at the chain of rocks, opposite the intake tower of the
St. Louis waterworks. From consideration of the curves which represent the averages appearing in tables C and D, it is made evident that the content of chlorine and of albuminoid nitrogen was considerably greater upon the Missouri side of the river than it was upon the Illinois side, and shows further that there was a greater difference between the two sides of the stream at the St. Louis pumping station during the season of 1900 than there was during the same period of the preceding year, that is, the year 1899. These differences between the proportions of chlorine at the different cross section points at the chain of rocks and also the seasonal variations of the chlorine at these points are exhibited in plate XIV which is to be hereafter introduced, and we will give a short description of that hereafter.

That is all in regard to plate IV.

Q. JUDGE SPRINGER: Professor, I call your attention to a paper designated as plate V. Please state whether that plate was made by you and if so, from what data?

A. Plate V was made by me and from the same data that was the basis of the lines and columns upon plate IV.

Q. The description of this differs only in respect to the
fact that in one way the data were illustrated by lines,
8417 and here by columns?

A. That is all right, but there is something more, and also by the fact that upon plate V we show cross-section proportions at Alton as well as cross-section proportions at the chain of rocks, and that the columns upon plate V represent the chlorine only for these various points and not also the nitrogen as albuminoid ammonia.

JUDGE SPRINGER: I now offer in evidence plate V to which you have referred and ask that it may be incorporated in the record as a part of your testimony in this case.

MR. JEFFRIES: Now I object to plate V being copied into the record and object to the witness testifying in relation thereto, or drawing any conclusions or making any determinations from it, for the same reasons stated in my objection to the introduction of plates II, III and IV.

A. Plate V is as follows:

COMPARISON OF THREE RIVERS

8419 THE WITNESS: Following down the series of columns from left to right, the differences between the black portion and the total height of column show the differences in content of chlorine between the two seasons; the proportions during the season of 1899 being represented by the entire column, and the proportions during the season of 1900 being represented by the black portion of the column. At points at which the proportions of chlorine in both seasons were practically the same, separate columns side by side are represented for showing more clearly the relations. In these cases the respective columns which ordinarily could be distinguished by the simple blackness in the one case, and the open, light column in the other, have been labeled 1899 and 1900 respectively.

The cross section variations in chlorine at Alton are shown quite clearly by the columns in group 3, as are also the differences in these variations between the two seasons, likewise the cross-section differences at the chain of rocks are shown in group 4. A comparion of the three rivers as to content of chlorine is shown in group 2. These represent features precisely the same as those shown upon plate IV, but present them in a slightly different form.

Now I think that is enough for that one.

Q. JUDGE SPRINGER: I now call your attention professor to the paper designated plate VI, and request you to state whether this plate was made by you and if so, upon what data you based it? 8420

A. Plate VI was made by me and represents graphically some of the averages which appear in tables C and D, which averages are based on the detail analyses, shown on tables 1 to 80 inclusive, or such part of these latter tables as cover the period June, July, August and September of 1899 and 1900.

JUDGE SPRINGER: I now offer this plate in evidence and ask that it be incorporated into the record as a part of the testimony of the witness.

MR. JEFFRIES: I object to the introduction of the plate in evidence and object to its being made a part of the testimony of this witness or of the testimony in this case for the same reasons stated in my objection to the introduction of plate V, and for the further reason that from the witness' statement,

it was only made up from a part of the analyses contained in the table of averages heretofore introduced; and for the further reason that it does not purport to represent or portray the character of the water in the Illinois river at the various points named on the plate during all times of the year, and for the reason also that it only portrays and represents, or purports to represent the character of the water in the Illinois river at the various points mentioned on the plate during the summer
8421 months of June, July, August and September of the years
referred to, while the winter months and spring months are omitted therefrom, so that no conclusion can be drawn from said plate that would represent the condition of the water with reference to the chemical constituents in the places referred to at all times of the year, and for this reason the plate does not represent the true character of the water of the river at all times and seasons of the year and cannot therefore be considered as constituting any evidence whatever, having no probative force and not being comparable with actual conditions existing and liable to exist at any and all times.

JUDGE SPRINGER: I move to strike out this objection for the reasons stated in similar motions in reference to the objections that have been made to the plates heretofore introduced, namely plates I to V inclusive, and for the further reason that it is impossible that one plate should contain all of the data presented in one of these tables of averages, the object in presenting these data graphically being to take portions of the data and graphically illustrate them on separate plates, for the purpose of showing in graphic form or in a pictured form the conditions which exist rather than to rely upon mere inspection of the figures contained in the tables upon which they are based.

Other plates will illustrate other conditions, and when
8422 they are introduced there will be a perfect representation
graphically of the various conditions which the detail analyses show to have existed at the time they were made, and further it is not contended by counsel that these plates represent anything other than the results obtained by the analyses which have actually been made and put in evidence in this case. We are not covering the earth, but we are only covering that part

of which is represented in the tables heretofore put in evidence and referred to upon each of these plates.

MR. JEFFRIES: I suggest to the court that if defendants are in possession of analyses showing the chemical constituents of the water at the various places during the entire year or any period that covers an entire year, that they and they alone will correctly represent the actual conditions, if they can be represented by the science of chemistry, and not by selecting one portion of the year and omitting the remaining portions of that year; and I also suggest to the Court that a plate of this kind and character can only be of service in the determination of the questions at hand when they graphically display the entire situation from one end of the year to the other, taking into consideration the conditions of water in the night time as well as the day, and taking into consideration the temperature of the water in the summer as well as in the winter and the changes and variations with reference to flow and volume of water each day and month throughout the year, and that only such tables can be of service to the court in making determinations, if tables of this character are to be relied upon so that the failure to graphically display from the plates now being offered in evidence the conditions throughout the year, renders them incompetent, irrelevant and of no probative force whatever. 8423

JUDGE SPRINGER: I submit that it is impossible for counsel for defendants to put in all of their testimony at the same time. We are now presenting testimony in detail. We intend before this witness leaves the subject entirely, before he quits the stand, to present other tables and other plates which will give a more extended result as to chemical conditions of the various waters under consideration, and I submit further that if counsel's objection is valid, that nothing would be competent in the way of chemical analyses of these waters unless we could analyze chemically every cubic centimeter of the water of the river that passes every moment at every point in the river between Bridgeport and the St. Louis intake, a task which is impossible, and defendants are not expected to accomplish impossibilities.

8424 MR. TODD: I desire to submit to the court in reply to the objections made by counsel for complainant, that while counsel for complainant in his objection as to the probative force of these charts may apply to the charts introduced in evidence by the complainant, the objection has no weight whatever when being applied to the charts which are being introduced in evidence as illustrating the testimony given by this witness based upon the chemical analyses in the tables heretofore offered in the evidence, and the objection if valid in any particular applies to the weight and not to the form of the evidence.

THE WITNESS: Plate VI is as follows:

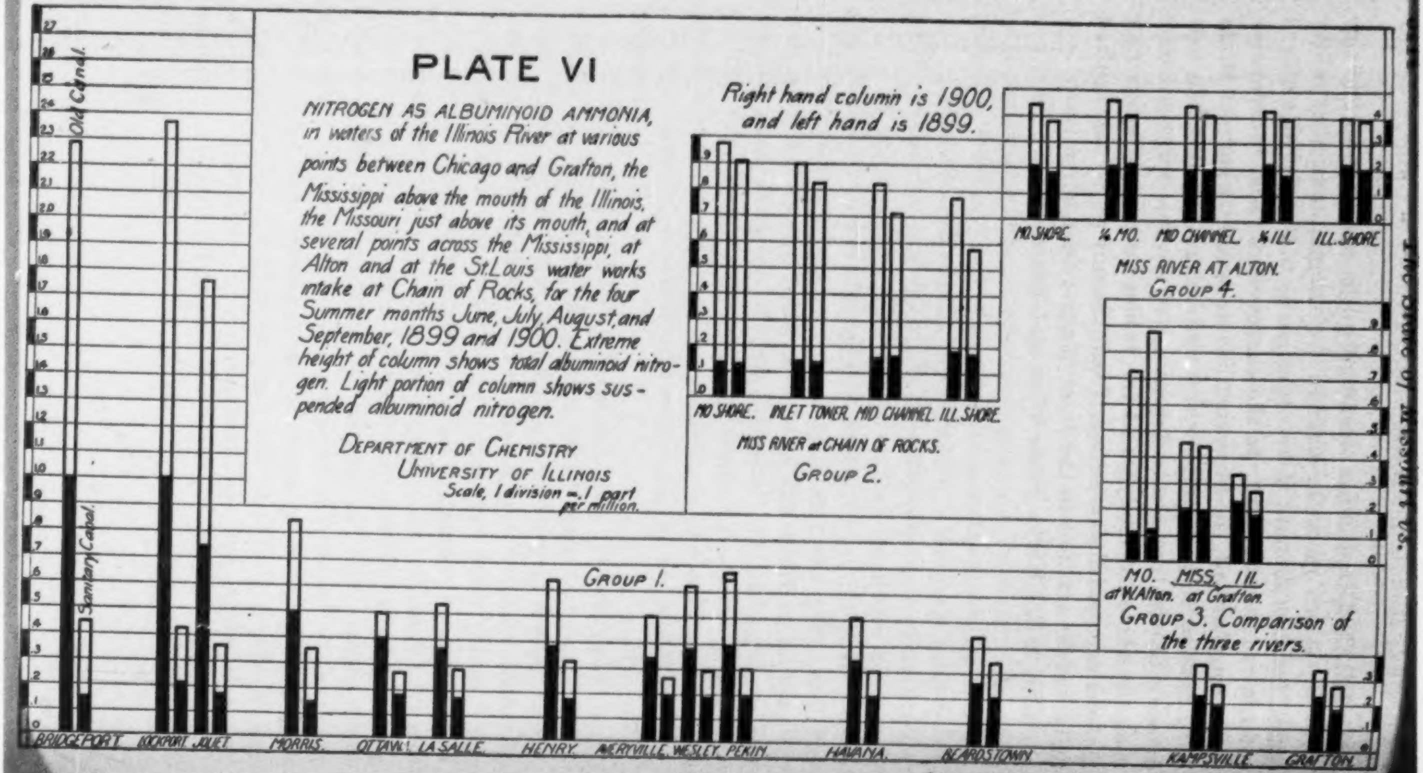

PLATE VI

NITROGEN AS ALBUMINOID AMMONIA, in waters of the Illinois River at various points between Chicago and Grafton, the Mississippi above the mouth of the Illinois, the Missouri just above its mouth, and at several points across the Mississippi, at Alton and at the St. Louis water works intake at Chain of Rocks, for the four Summer months June, July, August, and September, 1899 and 1900. Extreme height of column shows total albuminoid nitrogen. Light portion of column shows suspended albuminoid nitrogen.

8426 JUDGE SPRINGER: Now professor, will you please explain in detail what this plate was intended to illustrate?

A. Plate VI was made by me for the purpose of facilitating a realization of the significance of certain averages which appear in tables C and D, and in this respect is supplementary or rather complementary to that portion of plate IV which represents the proportions of nitrogen as albuminoid ammonia. It has the different lengths of the column to show the differences between the two years. The columns in this plate show in addition to the total albuminoid nitrogen, also that portion of nitrogen as albuminoid ammonia which is derived from albuminous substances contained in solution, and the difference between the black portion and the total height of each column represents the proportion of nitrogen as albuminoid ammonia derived from that portion of the albuminous substances which are in suspension in the waters.

Q. What period does this plate cover?

A. As all of the plates IV to XV inclusive, this plate covers the periods June, July, August and September, 1899 and 1900.

The successive shortenings of the columns as we proceed from near to the left hand side of the plate to the right hand,
shows the successive steps of decrease of nitrogen as
8427 albuminoid ammonia as we proceed down these streams
from the neighborhood of Chicago, that is Bridgeport and Lockport, to the mouth of the Illinois river at Grafton, and shows moreover, the notable increase in the proportions of these substances contained in the waters of the Illinois river just below Peoria.

Moreover, the differences between the two seasons, that is the period June, July, August and September of 1899 and the same months of 1900, readily appear on comparison of the right hand column with the left hand column in each set of two across the bottom of the plate. The very considerable difference between these columns showing the very considerable decrease in proportions of albuminoid nitrogen effected for the season 1900 by the dilution consequent upon the opening of the Chicago main drainage channel, and the discharge of lake water through it into the Desplaines valley. That this has not during the period in question brought about any notable increase in the proportions of nitrogen as albuminoid ammonia in that portion of the waters of the Mississippi, which passes down from the vicinity of Grafton to the chain of rocks near St. Louis toward the Missouri bank, is evident from an inspection of the columns of group 4 and group 2.

Q. Professor, I now hand you two papers, one designated
8428 as Plate VII, and the other as Plate VIII, please state
whether these plates were made by you and if so upon what data they were based?

A. Plates VII and VIII were made by me. They represent certain data which appear in the tables of averages in tables C and D, the detailed analyses of which appear in tables 1 to 80 inclusive, or rather in such portions of tables 1 to 80 as cover the four summer months, June, July, August and September for the years 1899 and 1900.

These two plates VII and VIII represent in general similar features to those already referred to in the descriptions of plates IV and VI, but the particular substances represented upon Plates VII and VIII are the total organic nitrogen, that derived from substances which are in solution, that derived from substances which are in suspension, and the sum of the two for the real total.

JUDGE SPRINGER: I now offer in evidence these two plates VII and VIII and ask that they be incorporated into the record as part of the testimony of this witness.

MR. JEFFRIES: I object to plate VII being incorporated into the record for the reason stated in my objection to plate VI, and for the further reason that it does not show what season
of the year the samples were taken which are graphically
8429 represented by the plate, and I object to the incorporation
of Plate VIII into the record for the same reason mentioned in my objection to the incorporation of Plate VI into the record.

THE WITNESS: Plates VII and VIII are as follows:

8432 Q. JUDGE SPRINGER: Please state professor, the periods covered by Plate VII?

A. The periods covered by Plate VII, are the four summer months, June, July, August and September, 1899, and the same months of the year 1900.

MR. JEFFRIES: In view of the last answer of the witness I withdraw that part of my objection which refers to the table, as not showing the time the samples of water were taken, the analyses of which are graphically set forth on the plate, but I still object to the incorporation of the plate into the evidence for the same reason contained in my objection to the introduction of Plate VI.

JUDGE SPRINGER: Now professor, please state what these two plates are intended to illustrate?

A. They are intended to illustrate, by a representation of the figures of the tables of averages C and D, the changes which take place along the course of the Illinois river and the Desplaines river and the Illinois and Michigan canal and the Sanitary Canal from Chicago to the mouth of the Illinois at Grafton, in the proportions of the total organic nitrogen, and also to show the relative quantities of total organic nitrogen in the water of the three streams, namely, the Illinois river, Missouri river, and the Mississippi river near the point at which
8433 these two streams come together, and to show the variations across the stream of the Mississippi river at Alton, and opposite the intake of the St. Louis waterworks at the chain of rocks, and to represent the difference between these two years for the period indicated.

Q. In reference to what?

A. With reference to the effect of the opening of the Chicago main drainage channel upon the waters of the Illinois and such portion of the Mississipi river as extends from the mouth of the Illinois to the intake tower of the St. Louis waterworks. The considerable differences between the right hand and left hand column in each pair in plate VIII show how much less was the content of nitrogenous organic matters as represented by the total organic nitrogen in the summer period referred to above, of the year 1900 as compared with the same period of the year 1899, the latter being the period before the opening of the Chicago main drainage channel and the former the period subsequent thereto.

Inspection of the two columns at the lower right hand corner of plate VIII shows graphically the relation between the figures which appear in tables C and D, representing the average proportions of total organic nitrogen, and that contained in substances in solution in the waters of the Illinois in 1899
8434 and in 1900.

Inspection of the columns represented in group 3 serves to show that the proportions of total organic nitrogen contained in the waters of the Illinois river at its mouth at Grafton, in 1900 was very considerably less, in fact, but little more than half as much in 1900 as in 1899. Same comparison of the next two columns which represent the proportions in the Mississippi river shows, that in it also the proportions for the summer period of 1900 were considerably less than during the same period in 1899, although the difference is not proportionally so great as in the case of the waters of the Illinois.

The third set of columns in this group represent the conditions with respect to the total organic nitrogen in the waters of the Missouri river. These columns serve to represent figures which appear in tables C and D, and express the fact that in the waters of the Missouri river in 1900 there was a greater proportion of total organic nitrogen than in the preceding year, that is the same period for the year 1899, but to those there must be noted the fact that the period for the Missouri river in 1899 was not so long as the period for the year 1900, for the reason again that the collections in the Missouri river did not begin in 1899 until July 10th.

8435 Cross-sections of the Mississippi at Alton shown in Group 4, show that the proportions clear across the stream in 1900, were considerably less than the proportions of total organic nitrogen contained in the waters of the Mississippi river at this point during the preceding year, the year 1899.

Consideration of the columns of group 2 show that the relative proportions at the different points across the stream at the chain of rocks, wer [illegible]t much different in the year 1900 from what they had been in the year 1899, although the total proportions at each of the four points across the stream were less in 1900 than in 1899.

Plate VII represents similar data by means of lines and curves instead of the columns, and will probably need no further explanation than that just given in respect to Plate VIII.

The total organic nitrogen referred to in these tables and in these plates and in the tables in which the figures represented upon the plates appear, is contained as a constituent of organic matters, particularly such organic matters as are contained in animal substances, and which are essential constituents of all living things, including micro-organisms as well as all
8436 other and irrespective of size, or the animal or vegetable
character, except that in general a greater proportion of nitrogen is contained in animal substances than is contained in most vegetable organisms or the substances in vegetable organisms which in particular contain the nitrogen in organic combination.

It includes that just referred to above and in the earlier plates as nitrogen as albuminoid ammonia, and in general it is from two to three times as much as the latter.

The dissolved organic nitrogen is of course derived from these nitrogenous organic matters which are commonly in solution in the water, while the total includes not only this, but also that which is contained in matters which are suspended in the water. These comparisons further give expression to the fact that the nitrogenous organic matters in solution which are here represented by the term "organic nitrogen in solution" are contained in the Illinois river water in greater proportion than in the waters of the Mississippi or in the waters of the Missouri, but it is noticeable that the difference between these streams has been considerably less during the summer of 1900 than it was during the summer of 1899. In the waters of the Missouri river there was somewhat more in 1900 than 1899, but the difference is slight. For the Mississippi and the Illinois, however,
8437 there are as represented, considerable differences, indicating a better condition of their waters in this respect during the summer of 1900 than during the summer of 1899. The striking differences between these three streams with respect

to the proportions of the nitrogenous organic matters becomes clearly manifest upon inspection of the unshaded portions of the columns of plate VIII.

Q. Professor, I now hand you three papers designated as Plates IX, X and XI. Please state whether these plates were made by you, and if so from what data they were compiled and made?

A. I made these three plates, Plates IX and X, and XI, and they were made as representations of the figures appearing in the tables of averages covering the four summer months, June, July, August and September, 1899 and the same months in 1900, which averages appear in tables A and D, and represent the detailed data which appear for these two four months periods, in the tables 1 to 80 inclusive.

JUDGE SPRINGER: I now offer these three plates in evidence and ask that they be incorporated in the record as part of the testimony of this witness.

MR. JEFFRIES: I object to the introduction of Plates IX, X and XI and to their incorporation into the record as part of the testimony of this witness, for the same reasons stated in my objection to the incorporation into the evidence of plates VI, VII and VIII. 8438

THE WITNESS: The plates, IX, X and XI are as follows:

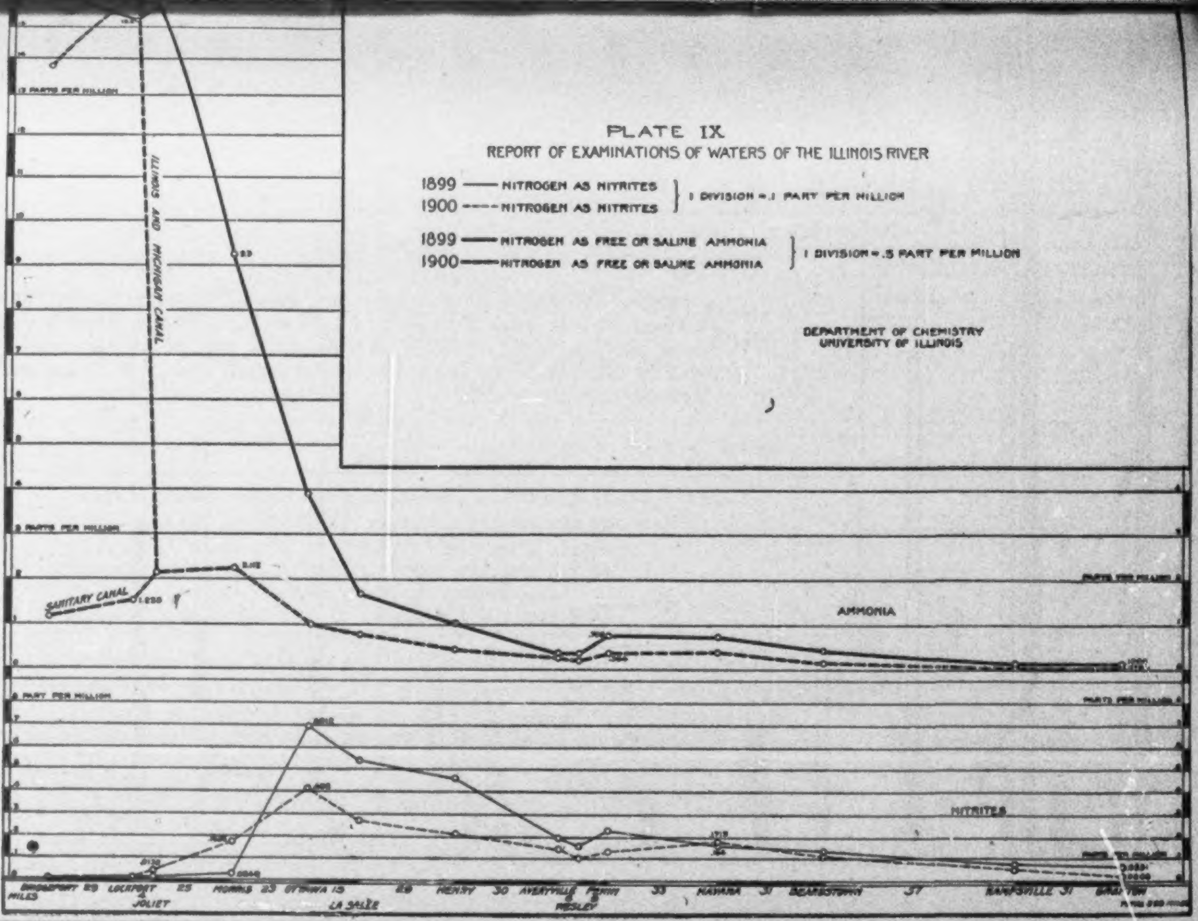

PLATE IX

REPORT OF EXAMINATIONS OF WATERS OF THE ILLINOIS RIVER

AT GRAFTON.

8442 JUDGE SPRINGER: Professor, you will now please state what facts are intended to be illustrated by these figures and what significance you attach to them?

A. Plates IX, X and XI, represent the proportions of nitrogen as free or saline ammonia and of nitrogen as nitrites, contained in the waters of the Illinois and Michigan Canal, the Sanitary Canal, the Desplaines river and the Illinois river at various points between Chicago and the mouth of the river at Grafton, except that the data which are given generally upon the single plate IX, are separated for presentation in the form of columns and appear, nitrogen as free ammonia upon Plate X, and nitrogen as nitrites on Plate XI.

After what has been said concerning similar plates representing other important constituents, but little explanation is needed in order to understand the meaning and significance of the curves of plate IX, or the columns of plates X and XI with reference to the purification of the stream. The total organic nitrogen and the albuminoid nitrogen referred to in the descriptions of plates IV, VI, VII and VIII represent largely waste organic matters which may be derived from either vegetable or animal sources or both. All vegetable and animal organisms contain as essential constituents, substances which in their original condition, and also in certain various stages of decomposition are classed as nitrogenous organic matters.

8443 Such matters are included in feces and urine, in waste from the household, in wastes from all industries which utilize plant and animal substances and products as well as in the vegetable substances contained in soils, and which accumulate in swamps and in forests. Those substances which make sewage and animal waste in general offensive to the senses and dangerous to the health are, as a rule, nitrogenous organic substances, either living organisms or the products or wastes of living things. The natural processes of purification of sewage and similar organic wastes involve the oxidation of these nitrogenous matters. The first stage in the purification process includes such a decomposition of these substances and the breaking down of the molecules of the complex proteid bodies, as results in the liberation of a portion of the nitrogen, together with the hydrogen in the form of ammonia. This may remain merely

dissolved in the water, or it may unite with acids, particularly with the carbonic which in these decompositions of the organic
matters may be formed simultaneously with ammonia,
8444 and thus appear as a salt of ammonia, or corbonate of ammonia. Ammonia is not in general contained in the surface waters in considerable proportions except it be derived from the sources above mentioned, or it be formed by the reduction of nitrates and nitrites when these substances under some conditions are in contact with decomposing organic matters.

The proportions of free ammonia contained in the water of the stream or in sewage, indicates on the one hand the relative quantity of refuse matters contained, and shows the stage of decomposition or on the other hand, it may represent the relative proportions of reduction of nitrites and nitrates. In this reduction process a considerable portion of the nitrogen which was at one time present in the water in the form of nitrates or nitrites, may be wholly lost, so far as the possibility of analytical determinations are concerned, by conversion into the element nitrogen, which as a gas may in part remain dissolved in the water, or it may be discharged from the water into the air in a gaseuos state.

8445 Referring to Plates IX and X, we may observe that in 1899 a considerable proportion of nitrogen as free ammonia was contained in the water of the Illinois and Michigan canal, and that although the proportion contained in the Desplaines river at Joliet was considerably diminished through mixing with the waters of the upper Desplaines river, yet considerable proportions of free ammonia were found in the river as far down as LaSalle, but that the diminution still proceeded as we passed down the river until we find the minimum at Averyville. Below Averyville the free ammonia increased in proportion again, reaching the maximum at Pekin, diminishing then more rapidly and continuously until the mouth of the river at Grafton is reached. The curve for 1900 shows of course the effect of dilution with lake water in the sanitary canal, that is the proportions of nitrogen as free ammonia never were so great in the water flowing into the upper end of the canal and past the points between that and Grafton as they were in the preceding year in the Illinois and Michigan Canal and the Desplaines

river and the Illinois river. Otherwise the curves show similar features, that is the very rapid diminution of free ammonia until we reach Averyville shows that the natural decomposition of the organic matters is taking place very vigorously in the upper reaches of the stream, but this action diminishes as we proceed down stream. The indication being that the
8446 diminution of the bacterial action is caused mainly by the exhaustion of the nutrients, that is, the supply of substances which are being converted by bacteria through ammonia into other innocuous forms of matter and which may be regarded as the food supply of the bacteria, is more rapidly diminishing.

It is notable that the proportion of free ammonia increases again below Averyville, but afterwards diminishes until we find at the mouth of the river considerably less than elsewhere along the course of the stream and less during the summer of 1900 than during the summer of 1899.

Upon Plate IX there are two curves, and upon plate X various columns representing the proportion of nitrogen as nitrites. Nitrites are oxidation products derived from the nitrogenous organic matters above referred to. In the conversion of objectionable and harmful nitrogenous organic matters into innocuous substances, the nitrites mark a stage following that which is indicated by the presence of the free ammonia.

The curve for 1899 shows the maximum content of nitrites at Ottawa. From thereon considerable diminution occurs until we reach Averyville and Wesley, but beyond that there is again an increase. We find the maximum at Pekin, beyond which there is a gradual decrease until we reach the minimum
8447 at the mouth of the river at Grafton.

The two maxima indicate the two zones in the river at which the second stage of the natural purifying processes is most vigorously under way.

Referring now to the curve for 1900, it becomes evident that the increase in the proportion of nitrites becomes marked very much nearer the source of the sewage, that is, since most of the sewage has been diluted before it is discharged into the Desplaines river valley, those natural decompositions and oxidations of the organic matters which result in the formation of nitrites and subsequently nitrates, have begun vigorously at a point much nearer Chicago.

The point at which the maximum quantity of nitrites is found during the summer of 1900 is again at Ottawa, as during 1899. From there the curve varies in general in the same direction, but it is notable that the minimum is less than during the earlier season and that the maximum never reaches the high proportion found in 1899.

Consideration of the curves and columns shows that the zones at which the purifying action takes place with the greatest vigor are in the vicinity of Ottawa, and the stretch of river between Pekin and Havana, under both sets of conditions, that is, those conditions prevailing during the summer of 1899 and those prevailing during the summer of 1900 or both before
8448 and after the opening of the drainage canal.

It is evident then that so far as the significance of nitrites is concerned, those purifying processes which effectively destroy the nitrogenous organic matters introduced into the waters of the stream either in sewage or in other ways, enter upon the decomposition earlier in their course of transit between Chicago and the mouth of the river, and the activities which bring about these changes reach their maximum at points no further down the stream since the opening of the Chicago main drainage channel than they did prior thereto.

MR. JEFFRIES: I move to strike out all of the conclusions and statements of this witness as drawn from and placed upon the plates VI, VII, VIII, IX, X and XI for the reasons stated in my objection to the introduction of the plates into evidence, and their being incorporated into the testimony of this witness.

ADJOURNED until 10:00 A. M., following morning, Thursday, October 15th, 1903.

10:00 A. M., Thursday, October 15, 1903.

8449 Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ARTHUR W. PALMER,

resumed the stand for further direct-examination by Judge Springer and testified as follows:

Q. Professor, at the time of adjournment on yesterday you were giving an explanation of plates IX, X and XI, which have already been read in evidence. Have you any further statement to make in regard to those plates?

A. I was not quite through with them and will proceed. Study of the various figures of the tables and the curves and columns of the plates reveals the fact that in each of the summers in question, there was less nitrogenous organic matter contained in the water of the Illinois river at Ottawa just above the mouth of the Fox, than was in the Illinois river water at points farther down its course, except at Averyville, and at Grafton. This may in part result from incomplete mixing in
the upper stretches of the river, but is undobutedly due
8450 in part to the fact that organic matters of animal
origin such as constitute the chief organic matters of sewage, are more easily susceptible to the putrefactive and oxidizing influences which bring about the purification of water, while vegetable matters, which constitute the greater part of the organic matters found in the natural waters of swamps and streams, such as are contributed in larger proportion to the Illinois by its tributaries and by the run-off from its own slopes, are less easily decomposed and persist in the water of the lower river in greater proportion.

Moreover, vegetation, particularly of the minuter and floating forms, that is the plankton, is more abundant in the waters of the lower stretches of the river, from LaSalle down. The nitrites and nitrates produced abundantly in the waters of the upper part of the river through the decomposition of the nitrogenous organic matters of sewage are in turn utilized by the vegetation and in part their nitrogen is built up into more stable and less objectionable nitrogenous organic matters which remain floating or dissolved in the water and appear in the analytical results but must be regarded with much less disfavor and objection than would be accorded a like proportion of nitrogenous matters of animal origin.

Q. Professor, I now call your attention to plate XII and plate XIII. Please examine these two plates and state 8451 whether they were made by you and if so, from what data they were made?

A. I identify these plates XII and XIII, as plates which I made, to represent graphically certain averages which appear in tables C and D, which averages were made from those portions of tables 1 to 80 inclusive, which represent analyses of samples collected during the four summer months, June, July, August and September, 1899 and the same months of year 1900.

JUDGE SPRINGER: I now offer these plates in evidence and ask them to be incorporated into the record as a part of the testimony of this witness.

MR. JEFFRIES: I object to the introduction of these plates in evidence, and to their being incorporated into this witness' testimony, or to their being incorporated into the testimony of this case for the same reasons stated in my objection to the introduction into the evidence and the incorporation in evidence of plates VI, VII, VIII, IX, X and XI.

THE WITNESS: The plates are as follows:

8454 Q. JUDGE SPRINGER: Now, professor, will you please explain what is intended to be illustrated by these plates and what bearing they have upon the investigations which you have made during the periods indicated, namely the four months, June, July, August and September 1899 and the same months of 1900?

A. Upon plates XII and XIII are shown curves and columns representing the proportions of oxygen consumed by the water in the Illinois river at various points, as indicated on the other charts or plates, and a comparison of the waters of the Missouri river near its mouth, the Illinois at its mouth and the Mississippi just above the mouth of the Illinois, and cross-section determinations at Mitchell or the chain of rocks on Plate XII, and at the same points and also the cross-section at Alton, in Plate XIII. It is obvious from inspection of the curves and columns which represent the figures recorded in tables C and D heretofore read in evidence, that the water in the upper stretches of the river contains a great deal more of such organic matters as are easily susceptible to oxidizing agencies, than does the water in the lower stretches of the river. The diminution in 1899 was very rapid until we reached Ottawa and Averyville, below Averyville the quantity of oxygen consumed increased owing to the discharge of sewage and wastes into the river at Peoria
8455 and Pekin.

Below Pekin there is a continuous diminution in these matters until the mouth of the river is reached. Similar features appear when we consider the total oxygen consumed by the matters in solution in the water, that is in the filtered water. The curve for 1900 shows variations at different points along the river, and make manifest the fact that the proportion of easily effected organic matters in the water is considerably less than during the corresponding season of 1899, though there is not such a great relative diminution along the course of the river, for the reason that the initial dilution through the operation of the sanitary canal at once decreases the proportions or oxidizable matters in or near to Chicago and there is consequently less opportunity for diminution on the way down the river because the proportions at the upper end are already far less than they were in former times, that is times prior to the opening of the drainage canal.

Group 2 of plate XII, represents a comparison of the relative quantities of oxygen consumed by the waters of the Illinois river, those of the Mississippi river and those of the Missouri river. It is evident that the waters of the Illinois river contain considerably less readily oxidizable matter in the summer
8456 of 1900 than in the summer of 1899. In the case of the
Mississipi river water it is evident that the proportion of oxidizable matters far exceeds that contained in the Illinois river water at the mouth, and that the proportion is practically the same for the two seasons, namely, 1899 and 1900.

In the case of the Missouri river water the proportion of oxidizable matters is essentially the same in 1900 as it was in 1899, but in both years it is very much greater than the proportion contained in the water of the Illinois river. On the other hand, comparison of the proportionate quantities of oxygen required by dissolved organic matters shows that there is less required by the waters of the Missouri river than by the waters of the Mississipi river or those of the Illinois river, this appearing from the columns which appear in Plate XIII.

Q. What group?

A. Plate XIII, group 3.

Q. Can you make any further explanation of that then?

A. No, not at present—did you ask me whether I would?

Q. Yes.

A. I can if required.

Q. You may if you desire, make it now, or state it?

8457 A. I wasn't quite through.

Q. Excuse me then, for interrupting you. Proceed then until you reach this point and then you can do so.

A. In 1899, as appears from this same group 3 of table XIII, the quantity of oxygen consumed by the waters of the Illinois river were considerably greater than in 1900, also by the Mississippi river water, more was required during the summer of 1899 than during the summer of 1900, but in each year the quantity required by the Mississippi river water was greater than the quantity required by the Illinois river water.

In answer to the question of counsel, I would say that the smaller proportions of oxygen required by dissolved substances in the Missouri river water, notwithstanding the fact that the total oxygen consumed by the Missouri river water was greater than that required by either the Mississippi or the Illinois river water, was due to the fact that the substances in suspension in the Missouri river water were more considerable in quantity, required more oxygen for their oxidation than did the suspended matters in the waters of the Mississippi river or the waters of the Illinois river.

Now group 3 of Plate XII and group 4 of Plate XIII show the relative quantities of oxygen consumed by water samples collected at the four points across the stream of the Mis-
8458 sissippi river at the chain of rocks or Mitchell. It is evident that the water along the Missouri shore and in the vicinity of the intake tower contains much greater quantities of organic matters than does the water which passes down near the Illinois shore.

On the other hand, in this latter group it is apparent that the dissolved, readily oxidizable matters contained in the water near the intake tower are less in proportion than those contained in the water near the Illinois shore.

Group 2 of Plate XIII, representing the cross-section at Alton, shows that the proportions of oxidizable matters at various points across the stream were greater during the year 1899 than they were during the same period of 1900, both for the totals and for that in solution, and shows further that the proportions of total oxygen consumed and that consumed by matters in susupension, were greater as we pass from the Illinois shore down which the Illinois river water flows, toward the Missouri shore, where the water in greater proportion is that from the upper Mississippi river.

Considering the evidence represented by the columns in group 1, and that of the curves in groups 2 and 3, plate XII, and the columns of group 1 and those of groups 3 and 4
8459 of plate XIII, it appears that the water passing down near the Missouri shore and passing the intake tower of the St. Louis waterworks is much more nearly like the water of the Missouri river than it is like that of the Mississippi river in its upper stretches or the Illinois river in its lower stretches.

MR. JEFFRIES: I move to strike out all the plates and tables of averages and all of the testimony of this witness, based on such tables and plates, for the reason that the table of averages does not properly represent the actual conditions of the water at all times of the year; for the further reason that these tables of averages conceal actual conditions existing at times when the condition of water in the Illinois river is much worse than is shown by the table of averages.

I move to strike the tables and plates out for the further reason that they are of such character as when applied to natural existing conditions are absolutely worthless to the court in the determination of the questions involved in this case, and while certain of the analyses might show a diminution of organic matter regardless of whether it be polluted matter or not, yet at the same time many instances occur where greater quantities of organic matter exist, and it will not do 8460 to say so far as the issues involved in this case are concerned, that the general average of the conditions existing throughout four months of a year can be applied to the river as a whole, and at all times of the year; that the analyses upon which the averages are based, and the plates are based, show at times much larger quantities of organic matter and do not appear to reduce those findings, and conceal them, clouded by a table of general averages made up of analyses of water taken at that time of the year, which is more favorable for the destruction of organic and other matters, and I move to strike out the tables and plates for the further reason that the witness has shown no knowledge in evidence of the sources from which the organic and other polluting matters come, which are found in the waters of the Illinois river, or the character of those polluting substances.

JUDGE SPRINGER: I object to this motion on the ground that it is principally argumentative, and goes to the weight of the testimony and not to its admissibility or its competency as testimony in this case.

8461 Q. Professor, I now call your attention to plate XIV, which I now hand you. Please state whether you made that plate and if so, upon what data you based it?

A. I made plate XIV, and the data which are represented here by means of curves are contained in the tables numbered 1 to 80, inclusive, referring to the points named in the plate, which tables have been heretofore put in evidence.

JUDGE SPRINGER: I now offer this plate in evidence, and ask that it be incorporated in evidence as a part of the witness' testimony.

MR. JEFFRIES: And I object to its being incorporated in evidence of this witness, or into the evidence in this case, for the reason that the defendants have as yet failed to show the purpose and object of the introduction of the plate, and for the further reason that the plate itself shows that it has from its face, no bearing upon the issues in this case.

I object to it also for the reasons heretofore stated in my objection to the introduction of previous plates from I to VI.

JUDGE SPRINGER: I move to strike out this objection for the reason that it is principally argumentative and goes only to the weight of the testimony and not to its admissibility or competency as testimony in this case.

THE WITNESS: The plate is as folows:

8463 JUDGE SPRINGER: Now, please state, Professor, what is illustrated by this plate and what bearing it has upon the condition of the waters which have been analyzed by you?

A. Plate XIV is supplementary to or complementary with plates IV and V, which were heretofore put in evidence. It exhibits the differences between the proportions of chlorine at the different cross-section points at the chain of rocks, and also shows the seasonal variations of chlorine at these points during such periods, as the tables corresponding refer to, as indicated by the years marked upon the plate and the months and days appearing in the scale at the bottom thereof. The small circles along the lines place the dates, and show also the proportions of chlorine by their relation to the vertical scale at the side of the plate. There appears in these curves seasonal variations in the proportions of chlorine, and differences between the proportions of chlorine contained in the water of the Mississippi river at the four different cross-section points, opposite the intake tower of the St. Louis waterworks. It also institutes a comparison between the proportions just mentioned, and the proportions contained in the water of the Missouri river at West Alton, and serves further to illustrate the point previously discussed, that the water near the intake tower and near the
8464 Missouri shore at the chain of rocks is more like the water of the Missouri river than is the water passing down at mid-channel, or that passing down toward the Illinois shore in this locality, that is opposite the chain of rocks.

Q. Please explain, Professor, any differences that may be disclosed by this plate XIV, at the different seasons or months of the years indicated?

MR. JEFFRIES: I object to the question for the reason that there has been no showing made by the defendants of the taking of samples from December, 1900, to Decmeber, 1901, and no showing of samples being taken in such manner as to authorize characterization on this plate of the actual conditions existing during any one year which may constitute all of 1899 or all of 1900 or a part of both years, and that there is nothing on the plate itself which will justify any such question.

Q. JUDGE SPRINGER: Proceed with your explanation, Professor?

A. Considering the various lines for 1900 which appear upon plate XIV, it is evident that the proportion of chlorine contained in the water of the Missouri river at West Alton, was greater at the dates indicated in January, 1900, than in February, and that in March the proportion is considerably less than in either February or January. Proceeding on through
8465 such portion of the year as this curve represents, we find slight increases and slight decreases from time to time, but that in August there was a more considerable increase in chlorine than during several months preceding, and that after a decrease again in the latter part of August and in the early part of September, the proportions of chlorine increase considerably, to be followed by a decrease near the middle of September which was again followed by a very considerable increase near the end of September, the latter increase being followed by a more considerable decrease to a date early in October, which is stated in the table from which these data have come, but at which date the collection of samples from this river was discontinued.

Q. That is for 1900?

A. 1900 we are referring to there.

Q. Those small figures at the bottom of the line indicate the day of the month which follow just below, do they not, at which the ascertainment was made, is that right?

A. The dates at the bottom of the plate represent the dates at which the collections were made, but in order to avoid crowding at certain points in the scale at the bottom of the plate some dates are merely indicated by lines, and not by figures.
8466 The figures all appear in table 73, which has heretofore been read in evidence.

Q. Now, upon what analyses was the other line, 1899, based?

A. The line marked 1899 represents the data of the analyses for the same river and the same point given in table 32, and covers the period, July 10 to December 29, 1899. It shows similar seasonal variations, the content of chlorine in this case being lowest in the summer months and increasing during the fall and winter.

Consideration of the other lines of plate XIV show that the waters passing down near the inlet tower of the St. Louis waterworks and near the Missouri shore opposite, are subject to the same seasonal variations, as regards content of chlorine, as those just described, with respect to the water of the Missouri river at Fort Belefontaine or West Alton, and show further that the water at these two points is more greatly like that of the Missouri river itself than is the water passing down at mid-channel, or that passing down toward the Illinois shore opposite the intake.

Q. Professor, I now hand you plate XV. Please state whether you made that plate, and if so upon what data it is based?

A. I made plate XV. It is based upon the figures given in tables C and D, which refer to the averages for the four summer months of June, July, August and September, 1899, and
8467 1900, which averages were made from the detailed figures found in tables 1 to 80, inclusive, heretofore offered in evidence, and the columns of this table represent by their proportions the figures of the tables of averages referred to, namely, tables C and D. The particular sets of figures of tables C and D represented upon this plate are those which pertain to the waters of the Kankakee river, the Fox river, the Big Vermillion river, the Sangamon river, the Illinois river at Averyville, and the Illinois river at Grafton for the two periods in question, and have been brought together in this plate for the purpose of rendering easy a comparison of the relative proportions of the different constituents named upon the plate as contained in the waters of the tributary streams, and the waters of the Illinois river at Averyvile and Grafton.

JUDGE SPRINGER: I now offer this plate XV in evidence and ask that the witness incorporate it into his testimony as a part of the evidence.

MR. JEFFRIES: I object to the introduction of plate XV in evidence, and object to its being incorporated into the evidence of this witness, or into the evidence in this case, for the same reasons stated in my objection to the introduction of plates numbered from VI to XIII, inclusive, and for the reasons stated in my motion to strike out all of the plates from I to
8468 XIII, inclusive.

I object further for the reason that the plate is confined solely to a comparison of the tributaries of the Illinois river, with the water in the Illinois river, and it is therefore irrelevant, incompetent and immaterial, having no bearing upon the issues involved in this case, and does not prove or tend to prove any issues involved; and for the further reason that if it should be considered material under any circumstances whatever, a sufficient number of samples were not taken from the tributaries to be comparable with those taken from the Illinois river.

I object for the further reason that it is based upon a table of averages, which as heretofore stated, conceals actual conditions of far greater importance than what may be considered the general average conditions, even if a general average can be obtained, in such manner as to be relied upon, and in such manner as to be of any probative force.

JUDGE SPRINGER: I move to strike out this objection for the reasons stated heretofore in reference to other objections to these plates.

THE WITNESS: Plate XV is as follows:

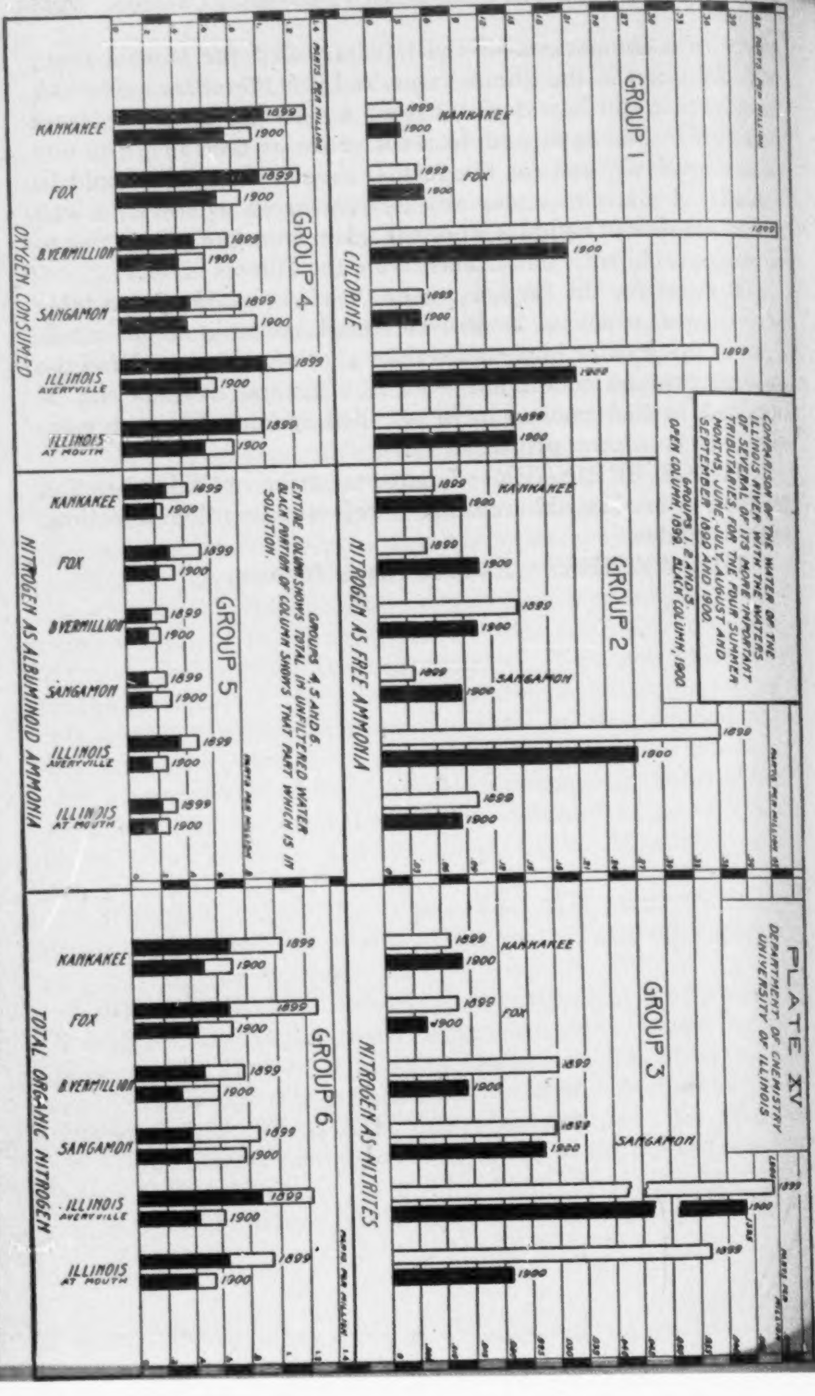

PLATE XV
DEPARTMENT OF CHEMISTRY
UNIVERSITY OF ILLINOIS

8470 Q. JUDGE SPRINGER: Professor, will you please state what facts are intended to be illustrated by plate XV and the several groups mentioned on that plate?

MR. JEFFRIES: The question is objected to for the same reasons stated in my objection to plate XV.

A. Plate XV is intended to represent by means of columns the averages which appear in tables C and D, referring to the proportions of chlorine, of oxygen consumed, of nitrogen, as free and as albuminoid ammonia, and as nitrites, and the total organic nitrogen in the waters of several different tributaries of the Illinois, and to facilitate a comparison of the proportions represented by these figures of tables C and D, with the proportions contained in the waters of the Illinois at Averyville and Grafton.

The comparison of these columns which merely represent the figures in the table of averages, renders evident at a glance the fact that the proportions of organic matters as represented by oxygen consumed, by albuminoid ammonia and total organic nitrogen, are even more considerable in the waters of the larger tributaries of the Illinois than they are in the waters of the Illinois at Grafton. Free ammonia and nitrites, however, are more
abundant in the waters of the Illinois river at Averyville
8471 than in the waters of the tributary streams, but the waters
of the Illinois river at its mouth at Grafton, contain less nitrogen as nitrites than is contained in the water of the Sangamon river, the proportion contained during this period of four summer months, June, July, August and September, 1900, being less than half as much as was contained in the corresponding period of 1899, and about three-fourths as much as was contained in the waters of the Sangamon river during the same period in 1900 and in 1899, and less than was contained in the waters of the Big Vermillion river during the corresponding period of 1899.

The waters of the Illinois river at Grafton contain considerably less nitrogen as free ammonia during these four months in 1900 than was contained during the same period in 1899, and the proportions in both years were less than the proportions contained in the waters of the Big Vermillon river in either year, although the Big Vermilion river water contined less in 1900 than it did in 1899. Moreover, the proportions of free ammonia in the water of the Illinois at Grafton during this period in 1900 is slightly less than the proportion contained in the water of the Sangamon for the same period and year, and still more considerably less than was contained in the water of the Big Vermillion river, the Fox river, and the Kankakee river, during this same period.

8472 Q. Will you please make similar comparisons as to nitrogen and free ammonia and nitrites, of the waters at Averyville in the Illinois river and the Kankakee river for the two years under consideration?

A. The proportions of nitrogen as nitrites and as free ammonia in the waters of the Illinois river at Averyville were very considerably greater than the proportions of nitrogen as nitrites or that as free ammonia in the waters of the Illinois river at Grafton in both years, and very considerably greater than the proportions of these substances contained in the waters of the Kankakee river during these periods and years. Consideration of the columns of group 4 representing the proportions of oxygen consumed, show that the waters of the Kankakee river and the Fox river required more oxygen than did the waters of the Illinois river at Grafton in both of these years, and that the waters of the Sangamon river required more oxygen in the year 1900, than did the waters of the Illinois river at Grafton in the same year. Comparison of the figures of group 5 shows similar facts with respect to the proportions of albuminoid ammonia, namely, that there was a greater proportion in the waters of the Fox river and in the Sangamon river in 1900, than in the waters of the Illinois river at its mouth at Grafton, and that in
8473 the year 1899 the proportions of nitrogen as albuminoid ammonia in the waters of the Kankakee and the Fox were considerably greater than the proportions of these substances in the water of the Illinois river at the mouth. Similar facts appear from consideration of the columns of group 6, referring to the total organic nitrogen. In both years it appears that the water in the Illinois river at its mouth at Grafton contained less total organic nitrogen than did the waters of the Kankakee or Fox river, and that in the year 1900 the water of the Illinois at Grafton contained less total organic nitrogen than was con-

tained in any one of the tributary streams here referred to, namely, the Kankakee, the Fox, the Big Vermillion and the Sangamon.

Q. I call your attention to plate XVI, will you please state whether you made that plate or not, and if so, upon what data it was based?

A. I made plate XVI. It represents the discharge of water of the Desplaines river at Joliet of the Chicago main drainage channel or sanitary canal at Lockport and of the Illinois river over the dam at Kampsville, 31 miles from the mouth of the river. The data relating to the flow of the Desplaines river at Joliet and the discharge of the sanitary canal at Lockport, were furnished me by the engineer of the Sanitary District, Mr.
8474 Isham Randolph, I believe is the name. The data concerning the discharge over the dam in the Illinois river at Kampsville were furnished me by the United States engineer in charge of the Kampsville dam and the improvement of the lower Illinois river, Mr. C. V. Brainard.

JUDGE SPRINGER: I will state to counsel that Mr. Isham Randolph will be introduced as a witness hereafter and will testify to these figures more in detail.

JUDGE SPRINGER: Now, I offer this plate in evidence, being plate XVI.

MR. JEFFRIES: I object to the introduction of the plate in evidence and object to its being incorporated into the evidence of this witness or incorporated into this case for the reason that there has as yet been no proof as to the exact volume of water passing down the river at Kampsville during the year 1900, or of the volume of water passing through the sanitary canal at the Beartrap Dam at Lockport and the Desplaines river at Joliet, and no evidence showing that these curves on this plate represent correctly the discharge of said stream, and I move to strike out the statement of the witness as to the source of his information because it is hearsay and not competent proof. This objection, however, as to the amount of discharges of the vari-
8475 ous streams stands only in the event that the defendants fail to prove the exact discharges of the rivers as represented by the plate.

I object to the introduction of the plate for the further reason that this witness has not qualified as a hydraulic engineer and has not qualified as being possessed of scientific knowledge on stream flows, and the relative effect of added and reduced volumes of water upon any given stream.

JUDGE SPRINGER: I move to strike out this objection for the reason that it goes to the weight of the testimony and not to the admissibility or competency.

THE WITNESS: Plate XVI is as follows:

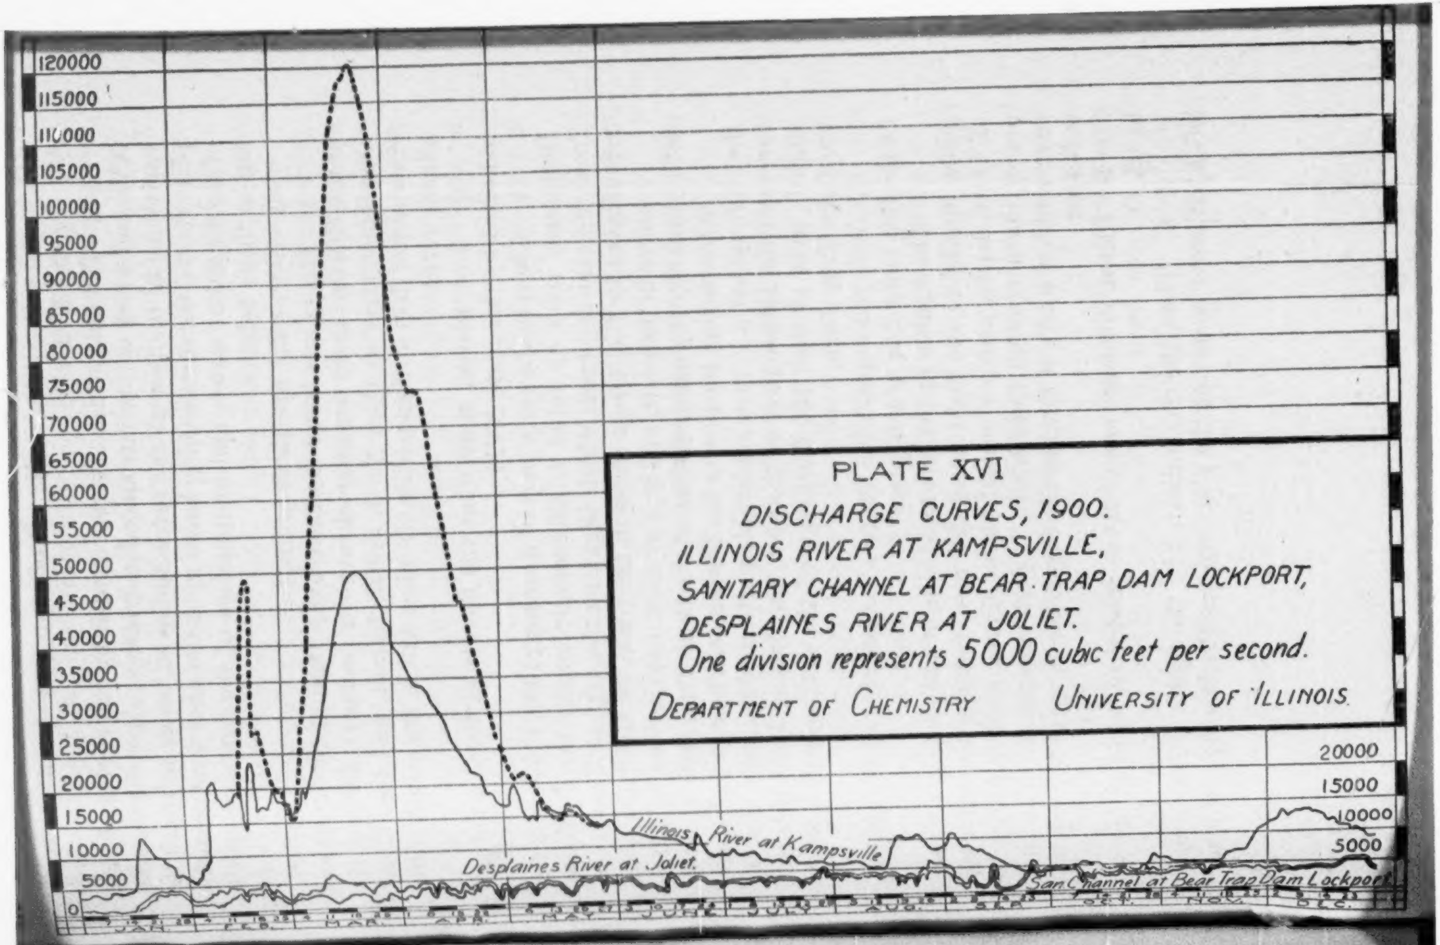

PLATE XVI

DISCHARGE CURVES, 1900.
ILLINOIS RIVER AT KAMPSVILLE,
SANITARY CHANNEL AT BEAR TRAP DAM LOCKPORT,
DESPLAINES RIVER AT JOLIET.
One division represents 5000 cubic feet per second.

DEPARTMENT OF CHEMISTRY   UNIVERSITY OF ILLINOIS

8477 JUDGE SPRINGER: Professor, you will now explain plate XVI.

A. The data which are represented by the curves of plate XVI, and which will be introduced in evidence, show the seasonal variations in the flow of the three bodies of water to which the plate refers, the curves being based upon the total measurements of the height of water, and computation of the flow corresponding to those heights.

Q. Now, what are those points?

A. The points being the Bear Trap Dam at the lower end of the Chicago main drainage channel at Lockport, Illinois, the Desplaines river at Dam No. 1, Joliet, Illinois, and the Illinois river at the dam at Kampsville, 31 miles within the mouth of the Illinois river.

Q. Now, please, state what the flow is at these points as indicated by this plate XVI?

A. Thus, in the early part of January, 1900, the flow in the Desplaines river at Joliet is exceedingly small; the discharge from the sanitary canal which began on the 17th of January is represented by the lowest curve in the plate, by the underneath curve in the plate, and it is evident that the opening of the
8478 canal by the manipulation of the Bear Trap Dam resulted in increasing the flow in the Desplaines river at Joliet, and that throughout a very considerable portion of the year, that is, for much the larger part of the year, the flow at Joliet was but slightly greater than the discharge of the drainage channel at the Bear Trap Dam.

Q. Will you explain the figures, the meaning of the figures on the left hand side of this plate?

A. The figures at the left hand side of the plate and those which appear at the right hand side also, indicate the volumes of water discharged per second, these figures applying to each one of the horizontal lines which is just beneath it. The line representing, where it touches the curve, the flow for the day so indicated.

Q. Please illustrate one of those conditions so as to apply to all.

A. Thus, the line indicated by the figure 10,000 at the left hand lower corner of the plate crosses the line representing the discharge of water in the Illinois river over the Kampsville Dam at about January 16th, the precise date being given in the tables of figures hereafter to be offered in evidence and shows that at or upon this date the discharge of the Illinois river at this point was 10,000 cubic feet per second. That there had 8479 been a somewhat sudden increase of the discharge upon a day or two preceding, and an increased discharge for a day or two following this date. Continuing along the line of the curve, the variations, that is, the increases and decreases are at any point and every point indicated by the position of the curve, with respect to the horizontal lines of the plate, while the dates are indicated by the relative position of the curve with respect to the figures at the bottom of the plate, and certain vertical lines which have been drawn to facilitate the comparison.

Q. At what season of the year is the flow greatest at Kampsville?

A. The flow is greatest at Kampsville in the latter part of March, that is, for this year 1900.

Q. This plate relates to 1900 altogether?

A. Yes, sir. The flow at that time being about 50,000 cubic feet per second.

Q. Then the figures represent the quantity of water going over the dam at Kampsville?

A. Yes, sir.

Q. Please state the volume of water passing over the Bear Trap Dam for the year 1900 as shown by this chart?

A. This chart does not show that. This chart shows by 8480 curves the daily flows, but not the yearly average. The yearly average I have stated somewhere else in figures.

Q. Well, take one of those averages when the lower dark line at the right hand side of the plate, March, 5,000, what does that indicate?

A. That indicates that the discharge from the drainage channel at the Bear Trap Dam was 5,000 cubic feet per second, or 300,000 cubic feet per minute.

Q. Now, Professor, I hand you plate XVII. Please state whether you made that plate, and if so, upon what data it is based?

A. I made plate XVII, and it represents the figures supplied to me by readers of the gauge at the C., B. & Q. bridge across the Mississippi river at Alton, Illinois.

Q. Who were those readers; what were their names?

A. I cannot give their names. Mr. Graham, who used to be superintendent of the Alton terminal line there, but I can look that up and give the exact initials and names. These are the official readings taken at the bridge and kept by the owners of the bridge; I think it is the C., B. & Q. now.

JUDGE SPRINGER: I offer this plate in evidence and ask that it be incorporated as a part of the testimony of this witness, being plate XVII.

MR. JEFFRIES: I object to the incorporation of plate XVII into the record for the same reasons stated in my
8481 objection to the incorporation of plate XVI.

JUDGE SPRINGER: I move to strike out the objection for the reasons stated heretofore in reference to motions of this kind.

MR. JEFFRIES: I move to strike out all of the tables of averages and all the plates based on those tables of averages for the reasons shown in plate XVI; that no reliance can be placed upon the table of averages, the volume of flow in the Illinois river ranging during the year 1900 from 50,000 cubic feet a second to less than 5,000 cubic feet per second.

JUDGE SPRINGER: I move to strike out this objection for the reason that it goes to the weight of the testimony and not to its competency or admissibility.

THE WITNESS: Plate XVII, is as follows:

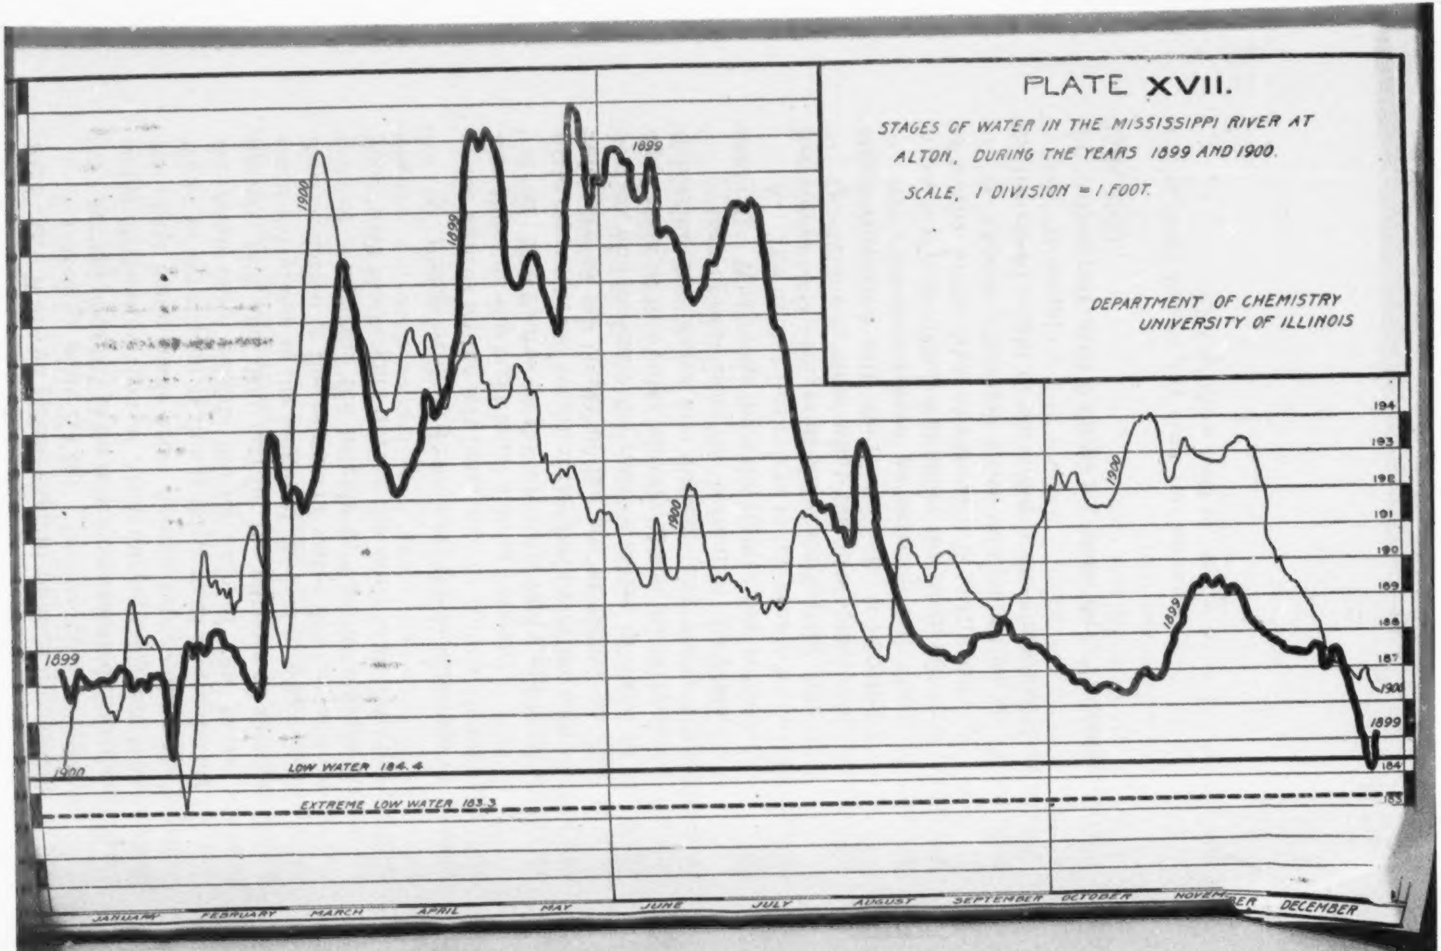

PLATE XVII.

STAGES OF WATER IN THE MISSISSIPPI RIVER AT ALTON, DURING THE YEARS 1899 AND 1900.

SCALE, 1 DIVISION = 1 FOOT.

DEPARTMENT OF CHEMISTRY
UNIVERSITY OF ILLINOIS

8483 Q. Will you please explain what is intended to be illustrated by plate XVII?

A. On plate XVII there are represented the stages of water in the Mississippi river at Alton during the years 1899 and 1900, the chart being made from figures representing the height of water in the stream at this point each 24 hours during the year, the mean daily heights during each of the years indicated, namely, 1899 and 1900, and for the purpose of showing the seasonal variations in the height of the water, which figures bear a direct relation to the volume of water flowing, and for the purpose of comparing the heights at various seasons during one year, with the heights during the same season during the other year.

Q. Please explain, Professor, the significance or meaning of the figures on the left hand side or column of this plate, and also those on the right hand side or column?

A. The figures on the left hand and right hand side of the plate represent the height of the surface of the water in feet with reference to the height of the sea at Biloxi, on the Gulf of Mexico, and indicates the relative stages of water in the Mississippi river at this point, namely, Alton, by reference to the lines indicating low water and extreme low water respectively, as they appear near the bottom of the plate.

8484 Q. What year does the lighter line refer to?

A. The lighter line refers to the year 1900, and the heavier line refers to the stages of water during the year 1899.

Q. Will you state what the low stages, the extreme low stages compared with the Biloxi data, is at Alton?

A. That this record as extreme low stage of water at Alton is a point 183.3 feet above the mean sea level on the Gulf of Mexico or the lake, whichever it is at Biloxi.

Q. And the increase above this point then would represent the increased height of the water at the time stated, at Alton?

A. It would.

Adjourned until 2:00 p. m., same day, Thursday, October 15th, 1903.

8485 2:00 p. m., Thursday, October 15th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

PROF. ARTHUR W. PALMER,

resumed the stand for further direct-examination, by Judge Springer, and testified as follows:

Q. Professor, have you made any other chemical analyses of the waters of the rivers of Illinois, and especially of the waters which have been under investigation since you took the stand as a witness, in this case, than those about which you have already testified?

A. I have.

Q. Just state, please, the circumstances which brought about those other investigations?

A. Well, as professor of chemistry in the university, it fell to me to examine many waters in connection with the instruction work of students, and also for the information of citizens, and also in connection with the work of the biological station of the university, which just at the time I began this 8486 work systematically, was located at Havana on the Illinois river.

My first work upon the Illinois river with the exception of some few examinations made many years ago when I was a student, began in the summer of 1894, the results of which examinations,—comparatively few samples being examined, were reported by me to the president of the university in 1897.

In the following year provision was made for a somewhat extensive series of investigations of the water supplies of the state, including not merely river waters and other surface waters, but also the ground waters, and the investigations at that time commenced included an attempt at a systematic study of the waters of the Illinois river.

Q. What year was that?

A. I have not mentioned any year yet, except 1894, and referring to the time of report of that work in 1897.

Q. Did the state of Illinois make any provision for more extended examinations of these waters?

A. It did.

Q. In what way?

A. The legislative assembly of Illinois in the spring of 1897, passed an act establishing a survey of the waters of the state and by this act directed the trustees of the univer-8487 sity to establish such survey, and made appropriation for the work in this survey.

Q. Will you cite that act of the Legislature of Illinois?

MR. JEFFRIES: We object to the statement that the witness has just made and object to the citation of the act of the Legislature of the state of Illinois with reference to the examination of the waters of the Illinois river prior to the opening of the Chicago drainage canal for the reason that it is incompetent, immaterial and irrelevant, not proving or tending to prove any issues involved in this case, the condition of the Illinois river water prior to the opening of the drainage canal not being under consideration in this suit.

Q. JUDGE SPRINGER: Please read the title of that act and the first and second sections of it?

A. Title of the Act, University of Illinois Chemical Survey of the Waters of the State of Illinois.

Q. No, that is not the title.

A. An Act to Establish a Chemical Survey of the Waters of the State of Illinois, approved June 7, 1897, in force July 1, 1897.

"Section 1. Be it enacted by the people of the state of Illinois represented in the General Assembly, that the trustees of the University of Illinois are hereby authorized and directed 8488 to establish a chemical and biological survey of the waters of the state in connection with said University.

Section 2. It shall be the duty of the university to collect facts and data concerning the water supplies of the state; to collect samples of waters from wells, streams and other sources of supply, to subject these samples to such chemical and biological examination and analysis as shall serve to demonstrate their sanitary condition, and to determine standards of purity of drinking waters for the various sections of the state; to publish the results of these investigations in a series of reports to be issued annually, or oftener, to the end that the condition of the potable waters of the State may be better known, and that the welfare of the people of the various communities of the state may thereby be conserved."

Q. What is the book from which you read?

A. Laws of Illinois, Radwell, 1897. All the laws of the state of Illinois passed by the Fortieth General Assembly, convened January 6, 1897; adjourned sine die June 4, 1897.

Q. State what steps were taken, if any, by the board of trustees of the University of Illinois for the purpose of carrying that act into effect?

MR. JEFFRIES: I object to the question as incompetent, irrelevant and immaterial, for the reasons stated in my objection to the reading of the act of the Legislature of the
8489 state of Illinois into the record.

Q. (Last question repeated.)

A. I was directed by the board of trustees of the University of Illinois to proceed to carry out the directions in this act of the Legislature.

Q. And what did you do in pursuance of that instruction?

A. I proceeded to make the investigations indicated in section 2 of the act, that is, to obtain data and information concerning the waters of the state; to obtain samples of water from the various different sources, and subject these to examination and to prepare the results thus obtained in the form of reports to the president of the university and the trustees.

Q. Did those investigations cover any point upon the Illinois river, the Desplaines river or the Mississippi or Missouri, or the sanitary canal or the Illinois and Michigan canal?

MR. JEFFRIES: I object to the question for the same reasons stated in the previous objection.

A. The investigations which I at that time began, included the examination of samples of water drawn from Lake Michigan, delivered at tap in the city of Chicago;

Samples of water from the Illinois and Michigan canal at Lockport;

8490 Samples of water from the Kankakee river at Wilmington;

From the Illinois river at Morris;
From the Fox river at Ottawa;
From the Illinois river at La Salle,
From the Big Vermillion river, near La Salle;
From the Illinois river at Averyville, or North Peoria;
From the Illinois river at Havana;
From the Spoon river at Havana;
From the Illinois river at Kampsville;
And later from the Illinois river at Grafton;
From the Mississippi river at Alton, and at Grafton, and at Quincy.

Q. JUDGE SPRINGER: Who selected the persons to take the samples of water at these respective places?

A. I did.

Q. What instructions, if any, did you give them in a general way? I don't want to go into too full details.

A. I gave them written and printed instructions as to the method of collecting samples, the precautions to be observed, and certificates also upon which they were to make certain entries as to the time of collection and other information
8491 concerning the source of supply and conditions prevailng at the time of collection.

Q. Were those instructions similar to those contained upon the certificates which accompanied the samples of water about which you have already testified in this case?

MR. JEFFRIES: I object to the question for the reason that it is incompetent, irrelevant and immaterial and has no bearing upon the issues involved in this case, and for the further reason that a copy of the written or printed instructions, or one of the samples of written or printed instructions is the best evidence, and I object to this character of testimony for the further reason that chemical analysis does not disclose the sanitary condition of water, and that this exaimnation was made without reference so far as this witness is concerned as to the amount of pollution, source of pollution, volume of water, or from a bacterial standpoint.

Q. (Question repeated.)

A. They were similar, but not identical therewith.

Q. Who were the persons selected by you to take these samples of water at the points indicated by you?

A. Do you wish me to name them

Q. No, not necessarily, if you can identify them without naming them?

8492 A. In most cases they were men who were afterwards selected to collect the samples of water for the investigations begun at the instance of the Chicago Sanitary District, the trustees of the Chicago Sanitary District.

Q. About which you have already testified in this case?

A. Yes.

MR. JEFFRIES: I object to the question and move to strike out both question and answer for the reason that none of the witnesses who did take samples for the Sanitary District of Chicago testified to ever having taken any such samples for Professor Palmer or for any one else.

JUDGE SPRINGER: The objection is not pertinent because the question does not embrace that.

MR. JEFFRIES: Read the question and answer?

(Question and answer read.)

MR. JEFFRIES: I will state here to the Court that if defendants are relying upon this testimony, it certainly was proper and competent at the time those witnesses were on the stand, to ask them the manner in which the samples of water were previolusly taken, and forwarded to Professor Palmer, and that the witnesses not having been questioned upon that period of time by defendants who placed them upon the stand, the statement of Professor Palmer with reference to the man-
8493 ner in which the samples were taken with reference to who took the samples, certainly is objectionable because defendants while having the opportunity to prove it, have failed to prove the manner in which the samples were taken.

JUDGE SPRINGER: I desire to suggest in reference to this objection that it was not necessary to ask these witnesses to testify in reference to the samples that were furnished to the University of Illinois, for the reason that those samples were taken in pursuance of an act of the Legislature of Illinois, and were a part of the official ascertainment by the authorities of the state of certain conditions which were provided for in that act, and it is not necessary in order to use the statistics obtained in that way, to prove by every person who took a part, and made a part of them, what he did, any more than it is necessary when you use the census reports of the United States, to prove from the census taker that he correctly enumerated the inhabitants contained in that report. It is a very different case we are presenting. We are presenting to you official data obtained by the authorties of a great state and made evidence by all the rules of evidence.

MR. JEFFRIES: Then I suggest that the evidence is without weight, is incompetent, immaterial and irrelevant, and these questions of a preliminary character are entirely out of 8494 place, assuming that Judge Springer is correct in his statement of the law. We are now dealing with what was actually found to be the conditions at the time and not with reference to what any official of the state of Illinois may have said with reference to conditions ascertained by him under and by virtue of any statute law of the state of Illinois, and in order to be able to place the proper light upon this testimony, we have the right, and the Court is entitled to strict proof upon those propositions, because it entails the sanitary condition of the water during the time the examination was made, and during the time covered by the report which I presume is intended to be introduced.

JUDGE SPRINGER: Counsel for defendants will present their case in such a manner that the Supreme Court will take cognizance of it, and we are responsible for any failure to establish minor conditions which counsel for the complainant may point out.

MR. JEFFRIES: I suggest to the Court that the necessity of proving the names of the water takers and of other preliminary matters in connection with the analysis of water during the period now under consideration, which is assumed by defendants' counsel, is sufficient to warrant an objection which is now made, that strict proof should be made in relation thereto.

8495 JUDGE SPRINGER: Counsel for defendants suggest that we will argue these questions if necessary before the

Supreme Court. We prefer now to put in the testimony in the case, the witness will therefore proceed to state who were the other persons, not engaged in taking the samples about which testimony has already been introduced.

A. I will have to look up those names.

Q. Well, where were they located?

A. At Chicago, the collector from the Chicago city supply was a person not engaged subsequently in collecting for the sanitary district, Henry Enlert was his name.

The collector at Wilmington on the Kankakee river was not the same person as subsequently collected samples analyzed for the sanitary district. I can name the person there if you desire?

Q. Yes, if you can, name him.

A. C. H. Kaehler was collector at Wilmington.

The Hon. A. E. Palmer, mayor of the town, collected samples for me at Morris.

The collector at Ottawa I will name later; I don't recall it at the moment. I have it on record.

The collector at LaSalle was the same, Dr. William Frazer.

8496 The collector at Averyville was the same, and under the direction of the superintendent of the waterworks,—circumstances precisely the same as for the investigation later carried on for the Sanitary District.

The collector at Havana was one of the force of the biological station. I will name him later. Miles Newbury, was his name.

The collector at Kampsville was the assistant United States engineer, C. V. Brainard, who has since collected samples for the sanitary district work.

The collector at Grafton was Mr. B. F. Robinson, the same man that collected for the subsequent investigations for the sanitary district.

Also the collector at Alton was the individual, Mr. George Brooks, who afterward collected samples taken on behalf of the sanitary district of Chicago.

The collector at Quincy was the superintendent of the waterworks, Mr. Dow R. Gwin.

I should have said that the collector at Havana, both from the Illinois river and the Spoon river was the same individual, Miles Newbury.

Q. State whether the bottles were prepared, filled and shipped in the same way as the bottles about which you
8497 previously testified in this case?

A. They were.

MR. JEFFRIES: I object to that question for the same reasons as given in my previous objection to this character of testimony, and while we may not deny that Professor Palmer obtained the chemical results upon the analyses which he says he did and which are contained in his report based upon the act of the Legislature of the State of Illinois, which he has read in evidence, and if this testimony has any bearing upon the questions involved in this case, it is plain to the Court that the fact that those analyses do not correctly describe and represent the sanitary condition of the water in the Illinois river at that time, and it is denied by the State of Missouri, and therefore we are entitled to strict proof upon that proposition with reference to all the formalities of collecting the samples the shipment of the samples and the analyses of the samples.

MR. TODD: I desire to suggest in reply to the objection made by counsel that aside from the admissibility if this evidence being offered under a legislative act of the State, it is admissible for another reason, and that is that in the examinations of Professors Teichmann, Keiser and Ravold, they saw fit to take parts of these reports and refer to them in
8498 their examination for the drawing of conclusions, and under the strict rules of evidence, where the complainant goes into any part of a document without offering it in its entirety, the defendants have a right to offer the entire document or report, and all the analyses upon which that report is made, as the record in this case will disclose by a careful consideration of the testimony of the three witnesses who testified for complainant.

MR. JEFFRIES: I will state to the Court that we have no objection to the defendants reading in evidence the entire articles that were referred to by Prof. Keiser, Dr. Teichmann and Dr. Ravold, or any other witness that the state of Missouri has placed upon the stand, or may place upon the stand. We submit, however, that we have a right to introduce that character of testimony and to refer to anything that the Sanitary District or the State of Illinois has said, because said against itself.

We submit further that there is no evidence that any of the testimony of this witness or the reports of the authorities under the act of the legislature in question, were referred to by any of the witnesses for the State of Missouri.

Q. JUDGE SPRINGER: When those bottles from the Illinois river and the other points that you have mentioned arrived at the University of Illinois, please state what
8499 you proceeded to do with them?

A. They were examined, the samples treated and analyzed in precisely the manner set forth in my testimony of the last three days, respecting the samples examined by me on behalf of the Sanitary District of Chicago.

Q. Did you enter the ascertainments of those analyses upon any records made by you?

A. I did.

Q. Have you those records with you?

A. I have.

Q. Will you please produce them?

A. Yes.

(Witness produces papers).

Witness produced certain tables entitled "Department of Chemistry, University of Illinois, Sanitary Water Analyses, parts per million" which constitutes a part of the report of the State Water Survey as made by the department of chemistry of the University of Illinois under the act of the Legislature of the State of Illinois, approved June 7, 1897, and in force July 1, 1897, heretofore this day read in evidence, which tables were made by witness Arthur W. Palmer, Professor of Chemistry, University of Illinois, and which tables shall be hereafter
8500 known in this evidence as "Department of Chemistry, University of Illinois, A. W. P., Table 1 to table 80 inclusive."

JUDGE SPRINGER: Now I ask that these tables be read into the evidence.

MR. JEFFRIES: I object to the reading of the tables just referred to in evidence for the reason that they are incompetent, irrelevant and immaterial, and for the reason that there is no evidence showing the manner in which the samples of water were collected, or at least showing how all the samples were collected, and no evidence showing the manner of shipment or the manner of packing and no evidence showing time elapsing from the date of collection until the date the analyses were made.

JUDGE SPRINGER: I desire to suggest that the tables themselves furnish the information which counsel assumes is absent, in many respects.

MR. JEFFRIES: And I suggest that the witness himself has stated that persons other than those who have testified, collected samples for him for the purpose of making these analyses, and inasmuch as the Act of the Legislature of the State of Illinois and the conduct of the officials in reference thereto is not binding upon the State of Missouri, and as the State of
8501 Missouri challenges the sanitary conditon of the water
of the Illinois river at the times mentioned in the tables, subsequent to January 17, 1900, we are entitled to all evidence bearing upon the sufficiency, the correctness and the accuracy of the analyses and all witnesses having any connection therewith, in order that they may be cross-examined; and for the further reason that defendants' evidence shows that chemical analysis alone is not to be relied upon in determining the sanitary conditon of water.

JUDGE SPRINGER: I move to strike this objection from the record for the reason that the tables themselves when read in evidence will disclose many of the facts which counsel assumes are wanting, and for the further reason that his objection is argumentative and goes to the weight of the testimony and not to its competency or admissibility.

MR. JEFFRIES: And I object to the introduction of the tables for the further reason that they contain analyses of water made from various other streams than the Illinois river, and therefore they are incompetent, irrelevant and immaterial, the sanitary condition of the water of the Illinois river alone being under determination in this controversy.

8502 JUDGE SPRINGER: I move to strike out the objection for the same reasons stated in my previous motion.

MR. JEFFRIES: And I object to the introduction of the tables for the further reason that it is not shown by this witness that all these chemical results were obtained from his own personal work.

JUDGE SPRINGER: The witness will explain later how these tables were prepared, and I asked for them now to be read in evidence.

THE WITNESS. The tables are as follows:

8503

CHEMICAL EXAMINATION OF WATER FROM LAKE MICHIGAN AT CHICAGO.

(Parts per 1,000,000.)

During periods of high water and from Jan 5th to July 11th the water was odorless, except Jan. 26th, when it was gassy. From June 19th to end of year it varied, but was generally musty. Color on ignition was nearly always brown.
